

Figure 4. Water surface profiles for flow over Flip-Bucket (left diagram upper nappe profile, right diagram lower nappe profile)

The distribution of pressures at the bottom along the flip bucket is an important design parameter for static purposes. It is equal to the sum of the static approach pressure head h_o plus a dynamic portion. Figure 5 shows the comparison between experimental and numerical results. Normalized parameter $H_p = (h_p - h_o) / (h_{PM} - h_o)$ where h_p and h_{PM} are the total and maximum pressure heads, respectively, plotted along the normalized stream wise coordinate $X_p = x / (R \sin \beta)$, where $x=0$ is located at the takeoff point, and $R \sin \beta$ is the stream wise flip-bucket length.

Figure 5. Comparison between computed and measured pressure head distributions at bottom

Conclusions:

One way to dissipate of the energy in large dams is using flip bucket at the terminal of over fall spillways. Improving in design parameters of a flip bucket will protect the tailrace from scouring of impacted jet. Numerical modeling and analysis of flow with free surface which passes over a curved boundary by the gravity force is a challenging problem in hydrodynamics. In the present research by using Fluent software, a flip bucket structure was numerically simulated. To simulate the geometry and verify the results, experimental tests which were conducted in a smooth channel by Roman Juon and Willi H. Hager (2000) were selected. $k-\varepsilon$ Standard turbulence model and VOF free surface model were employed in the model. The results jet trajectory properties and pressures in the bottom and its good agreement with analytical and experimental data in eight cases showed the ability of Fluent numerical model in modeling the flow over the flip buckets.

Abstract: What prevents the strategies from getting operational in organizations is that, strategies remain at general level or general actions and orientations. To alleviate this problem, the researchers who proposed balanced score card model presented the concept of strategy map in this model. Strategy map tries to represent the organization's strategy in the framework of cause and effect relationships and demonstrate how the organization's strategy can be transformed into measurable objectives and specific operations which should be followed by organizational units and organization's staffs. To implement its strategies, the academic center for education, culture and research (ACECR) as one of scientific and research institutes in Iran requires a strategy map to be prepared which will provide the essential framework for implementation of the designed strategic plans. In order to design the strategy map in the present study, we made use of the related literature, references, and opinions of experts, and we prepared 40 indicators for different aspects of balanced score card model. Afterwards, we put these indicators into a questionnaire and asked the ACECR managers to let us know their opinion regarding them. Analysis of filled questionnaires by Friedman test resulted in selection of 30 indicators to be put into strategy map, and the resultant ACECR strategy map was designed deductively since no similar one existed. Subsequently, quantitative measures and objectives were considered for each indicator. Ultimately the status of this institution after the first year of implementing the strategy was analyzed using the obtained indicators and we proposed several strategies for successful implementation of the strategy and reduction of existing gaps.

Keywords: Balanced score card; Strategy map; indicator; Measure

1. Introduction

Further need to systematic evolution has been considered by the gradual increase in organizational and management problems, thus scientific and research activities regarding this issue started from beginning of the twentieth century (Kim et al, 2008).

Emergence of strategic management was in the second half of the twentieth century, which is historically subsequent to appearance of scientific management; nevertheless, its evolution and establishment as a management style is relatively modern. Balanced score card model is among the methods for implementation of strategy in organizations and has attracted much attention of numerous companies and organizations in the recent decade (Ali-Ahmadi et al, 2006).

What justifies the emergence of balanced score card is to satisfy organizations' need to a strategic management system by which the role of physical and non-physical assets can be

simultaneously considered in goals and strategies of organization (Guifang, 2009). In addition to financial indicators as functional ones, guide and performance indicators are also considered in balanced score card model (Kaplan et al, 2008).

This model is a technique to transform strategy into action. In other words, it is a method to make operational the vision, mission, and strategies of organizations and its main perspective is to study the future vision of the organization. Balanced score card does not merely play the controlling role and its criteria are not utilized for description of previous performance; rather, these criteria are a tool to explain the organization's strategy and make it possible to reach organizational objectives through coordination of activities at different organizational levels (Kaplan et al, 2008; Woods et al, 2008).

Since many organizations indeed use financial and non-financial measurement indicators of performance with the purpose of gaining tactic feedbacks and controlling current activities as well as

short-term improvement, balanced score card emphasizes on use of these indicators as a part of an information system for employees at all organizational levels. Goals and indicators existing in this model are beyond a collection of financial and non-financial measurement indicators. In a top-down process, these goals and indicators have been derived from mission and strategies of working units (Shvstrandana, 2008).

Balanced score card transforms the mission and strategies of working units into concrete and measurable objectives and indicators. This model leads to equilibrium among the following indicators:

1. Between internal indicators which relate to stockholders and clients, and external indicators which are related to work processes, innovation, learning, and growth.

2. between functional indicators caused by previous activities and guide indicators which lead to formation of performance and future status of organization (Ebrahimi et al, 2009).

Implementation of strategy using BSC model requires the following steps (Kaplan et al, 2007):

- Determination of vision and mission;
- Communication and transfer;
- Programming, determination of desired values, and coordination of executive activities;
- Learning and strategic feedback.

According to Kaplan and Norton who proposed balanced score card, the key to successfully execute the strategy in organizations is that the organization's staff understand it; this in turn includes complex yet essential processes by which non obvious assets are transformed into concrete and obvious outputs. Strategy map is a useful and appropriate tool to fulfill this hard work. In other words, strategy map is a tool which makes a connection between the organization's strategy and the processes and systems which assist the implementation of strategy. This tool provides an organization's staffs a direct and clear insight to understand how their jobs and activities are ultimately connected to comprehensive goals of organization, so it coordinates them in accomplishing their jobs (Kaplan et al, 2000).

Indeed, strategy map forms the foundation of balanced score card; according to Kaplan and Norton, successful implementation of balanced score card is based upon strategy map, i.e. precise determination of cause and effect relationships among organization's strategic goals in four perspectives, including financial perspectives, customer, internal process, and growth and learning (Kaplan et al, 2000; Kaplan et al, 2009).

As the researchers who proposed balanced score card believe, the best way to draw the strategy map is to use top-down approach. Such an approach starts with analyzing organization's goal and destination, and draws the paths for reaching the mentioned destination. To this end, top managers of organization should first analyze the mission and values of organization, i.e. why this organization exists and in what values this collection believes. Afterwards, using this information, managers can determine the vision, i.e. what the organization intends to be according to its philosophy of existence. This vision must provide a clear reflection of organization's goal (cheng et al, 2008).

Similar to balanced score card, strategy map is useful for both profit companies as well as governmental and nonprofit organizations; since its four perspectives can be changed (increase or decrease) concerning the activity field of the organization, customer perspective can be regarded as the first perspective for nonprofit organizations. Therefore, a standard pattern exists for designing the strategy map, and similar to balanced score card this pattern has four separate perspective including financial perspective, customer, internal processes, and learning and growth. After designing the strategy, managers of organization can hence draw a strategy map suitable for their organization considering the nature and activities of their organizations (Kaplan et al, 2008).

In 13th November 1990, the Iranian Supreme Council of the Cultural Revolution (SCCR) approved a bill; according to its definition, ACECR is a bridge between university and society. This institution presently considers its main goal as realization of the ideals of Islamic Revolution in universities and higher education centers, accomplishing high goals of Islamic Revolution, consolidation of religious tendencies among students, development of technology using Iranian experts with the purpose of removing scientific and cultural dependencies, and establishment of the higher education system in universities based upon Islamic values. According to statute of ACECR, goals of this institution are as follows: 1. Development of research and vivification of research mentality in society to reach self-dependency; 2. Development of cultural issues in society through collaboration with Hawza and universities; 3. Development of applied and semi-industrial projects through connection with scientific and research centers in order to make use of research findings; 4. Accomplishing developmental and applied research; 5. Continuing research project in ACECR up to semi-industrial and industrial stage; 6. Providing scientific and technical services in different fields which are essential for society; 7.

Encouraging and attracting young and talented students and researchers, and programming and providing the required conditions and facilities for their scientific and research activities based on understanding real problems of society; 8. Holding official programs of scientific-practical courses according to rules of Iran's higher education.

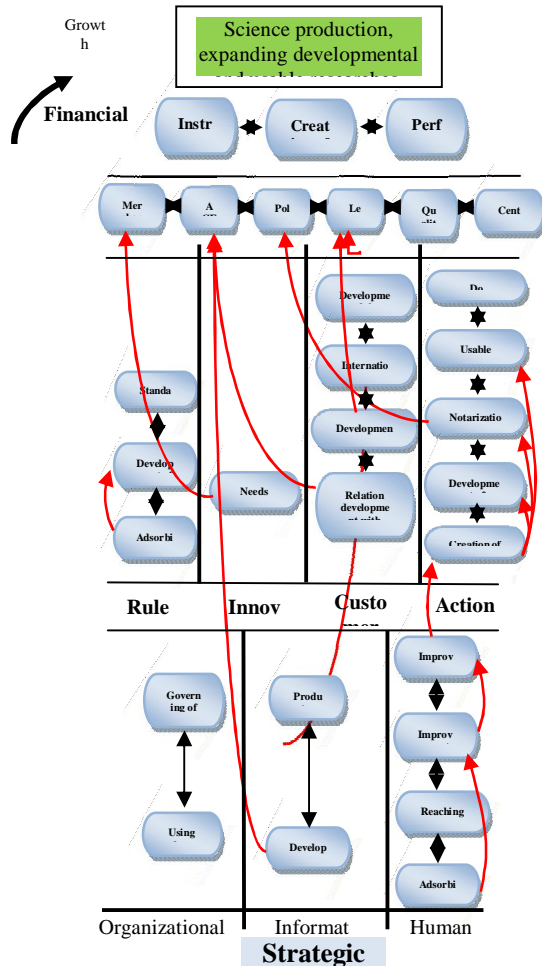

Fig 1: Strategic Map of ACECR

2. Methodology

The methodology used in this study is descriptive, analytic, practical, and also case study in ACECR. The population under study included ACECR managers in deputy of education and deputy of research, who were 210 individuals. The sample in this study was 132 managers of ACECR deputies of education and research based on De Morgan's table and according to random stratified sampling.

Table 1: Indicators extracted in order to design the strategy map

	Indicators title	Perspective
1	Gain improvement	Financial
2	Creation of new financial sources	Financial
3	Equipment development in accordance with program needs	Financial
4	Expansion of educational center with country region needs	Customer
5	Quality improvement with employment based perspective	Customer
6	Scientific level upgrade in non-government high education organizations	Customer
7	Identification ACECR to society (National, Regional, International)	Customer
8	Scientific poles development for science edges expansion	Customer
9	Identification of products merchants and ACECR services	Customer
10	Skilling short time educational courses	Internal processes
11	Fundamental, developmental and acting researches development	Internal processes
12	Co-increase creation in capacities and educational & research assists development between units and ACECR research centers.	Internal processes
13	Programmed acting researches and implementation of produced results	Internal processes
14	Production, adsorption and nationalization of needed technologies	Internal processes
15	Development of short time educational courses	Internal processes
16	Presenting educational services in international level and foreign students adsorption	Internal processes
17	Science-acting educational centers development with relative performances and experienced preferences	Internal processes
18	Providing base and development of communication and assists with international research & educational organizations	Internal processes
19	Identification of needs, research and education chances of country and region	Internal processes
20	Development of communication with Science and hygiene ministries to get needed Ruler certificates	Internal processes
21	Adsorbing of supports and assist of coherent government's organizations	Internal processes
22	Standardization of certificates and going to present international certificates	Internal processes
23	Improve the scientific level of ACECR members	growth and innovation
24	Improvement of staff members pyramid	growth and innovation
25	Reach to universal rules in employment of personnel	growth and innovation
26	Adsorbing of scientific power of elites	growth and innovation
27	Expanding perspective of notification of educational acts and ordering of notification sites	growth and innovation
28	Producing of book, software and educational sources for short time educational-experienced courses	growth and innovation
29	Using of new technologies and IT in ACECR	growth and innovation
30	Attention to Islamic rules and ACECR culture government	growth and innovation

Table 2: Balanced score card model of ACECR (education and research) (The indicators' numbers are in accordance with Table 1)

Indicators and measures of financial perspective:

Indicators	Main goals	Criteria	Quantitative goals (%)
1		Cost/Income	From 70 to 65
		Annual increasing of monies (%)	10
2		Annual increasing of received loans (%)	5
		New services income/all of income	5
		Ratio of store rotation	7 (Increase)
3		Territory skeleton space/available space	80

Indicators and measures of customer perspective:

Indicators	Main goals	Criteria	Quantitative goals
4		Created centers in unreached regions	Minimum 10 centers
5		Employment for students (%)	10 % increase
6		Scientific level within non-government educational organizations	Better rank
		Mean acceptance of graduates in MSc level	Minimum 20 %
7		Results of opinion projects	85 % national notification
8		Science and technology pole	one
		Science and technology pole	three
9		Doing environmental researching	Minimum 10 projects

Indicators of internal processes perspective:

Indicators	Main goals	Criteria	Quantitative goals
10		Increase of students numbers of experienced educational courses/students numbers of general educational courses	From current 20% to 30%
		Short time experienced courses numbers/all of courses numbers	75% to 85%
11		Scientific articles	Minimum one scientific-research article or 2 scientific-promotional article for any staff member
12		Number of courses that ran in accordance with experienced and scientific capacity of ACECR	Minimum 100
		Rank	One of 5 best organizations
13		Technology	6
		Rank of organization within all of organizations	Best
		Date of completing of network	Until end of program
14		Projects with assist numbers/all projects numbers	3%
		Projects with assist numbers/all projects numbers	5%
15		Numbers of all of students of short time and experienced educational courses	From 300 hundreds to 500 hundreds persons

Indicators	Main goals	Criteria	Quantitative goals
		Students numbers in special courses/numbers of students in experienced courses	Minimum 50%
		Numbers of approved courses	From 61 to 200 courses
		Numbers of international students/numbers of all students	1%
16		Acting in Islamic countries	Minimum 3 countries
		Research and identification of possibility of accepting science-acting students from regional countries	Minimum 10 projects
17		Increasing capacity of students reception	25000 students
		Accepting students in BS/Skill	From 40% to 60%
18		Treaty numbers with international organizations	Minimum 20 cases
19		Projects numbers	Minimum 10 projects
20		Increase of certificates numbers (%)	10%
21		Being member of committees and general and governmental societies	10% increase
22		Association with credible international companies to get justification	Minimum 10 companies

Indicators of financial growth and innovation perspective:

Indicators	Main goals	Criteria	Quantitative goals
		Annual educational capitation	70 hours
			2.7 to 6 (PhD)
			17.28 to 22 (MSc)
23		Composition of personnel based on educational diploma	29.26 to 34 (BS)
			12.08 to 14 (Skill)
			38.68 to 24 (Diploma and lower)
24		Professor assistant and higher levels/all of staffs	25%
			39.7 to 45 (official and agreement)
25		Composition of personnel based on employment	60.3 to 55 (full time treaty)
			13.7 to 20 (staff)
			86.3 to 80 (non-staff)
26		Inventor/staffs	3%
27		Results of opinion	30%
28		Sources numbers	20 title (annual)
29		Specialty of monies to new technologies and IT	20% increase
30		Numbers of mentions to any person for disregard of rules	0
		Numbers of published books and seminars about ACECR culture	Minimum 30

Data collection was fulfilled through library study, questionnaire, interview, and study of existing information resources. To study the related literature and access to similar studies, library study was used. Indicators, measures, and quantitative objectives

were extracted using questionnaire and interview, and data were analyzed using SPSS 16.0 software.

Considering the related literature and studying the vision, mission, long-term goals, and macro-strategy of ACECR in fields of education and research, 40 indicators were prepared for the first questionnaire as Likert scale and this questionnaire was handed in to ACECR managers nationwide. Friedman test indicated that mean values of 30 indicators out of the 40 indicators were significantly higher than average. After determining the indicators, several measures were considered for each indicator and the chosen measures for each indicator were determined in a questionnaire. Finally, some of quantitative objectives were determined from the organization's documentations and a limited number of them from interview. Considering the determined indicators and the cause and effect relationships, strategy map of ACECR was designed in fields of education and research.

After designing the strategy map, as well as extraction of indicators, measures and quantitative objectives, we compared the current status with pre-determined goals in first year of the program implementation through analysis of obtained indicators, in order to find out how much the strategy has been successfully executed in different mentioned perspectives in first year of the program implementation, and then we analyzed the existing gaps.

Indicators and measures in the two questionnaires were designed such that they were suitable for an institution such as ACECR. To this end, subsequent to initial design, the related questionnaires were analyzed in several stages and their relevance to the subject as well as being understandable was studied. After the final questionnaire was yielded, it was handed in to experts and its reliability was confirmed by Cronbach's alpha test.

3. Results

Considering the mentioned issues in previous sections, the strategy map, table of indicators, and table of balanced score card model of ACECR are provided in this section.

All analyses have been made based on existing documentations and opinions of managers. To avoid a long discussion, comparative graphs (existing status and expected program status for each indicator) have not been shown here. Following comparison and analysis, we have studied and analyzed the related existing gaps. Measures and quantitative objectives were designed in accordance with the strategic program and other documentations of ACECR; in case that no definition existed in the program, it was

obtained by interview with experts in the organization. Relationship of the extracted indicators with the goals existing in the ACECR strategic program was determined; nevertheless, to summarize the discussion, we do not mention the goals in table.

4. Discussion and conclusion

Analysis of strategy implementation status

In this section, we have analyzed the gaps subsequent to comparison of the level of fulfillment of indicators existing in the strategy map with their expected value in the program. To avoid long discussion, comparative graphs are not provided.

Financial perspective

In general, since more than 90% of ACECR's budget is provided by its income, this has led to remarkable importance of this perspective and the strategies of its subset.

From previous times, strategy of ACECR top managers has been physical development as well as ownership of ACECR assets, and this can obviously be observed from the indicators related to this perspective. The only existing problems are Iran's economical conditions, avoiding the payment of bank loans due to execution of contraction policies, and decrease in the budget allocated to ACECR because of change in government's policies, and executors of the program does not have a considerable role regarding these problems. Totally, performance of the program executors can be considered satisfactory and to a high extent in accordance to the program.

Customer perspective

Managers have satisfied the expectations regarding the indicators of this perspective as well as physical development of this institution in most Iranian cities and special attention to employment due to possessing the Organization for cooperation in graduates' employment whose responsibility is to provide job opportunities for those graduated from universities. Furthermore, possessing a wide network of scientific-practical centers nationwide has to some extent satisfied the society needs in this field. Also, the existence of such centers plays a major role in making people familiar with ACECR. Generally, indicators of the customer perspective have been in agreement with the program.

Internal processes perspective

The main viewpoint of ACECR managers in this perspective has been to specialize the activities. The second issue is entering the international arena, which requires fundamental changes in different perspectives; no specific output has been yielded in spite of holding numerous meetings, formation of

different workgroups, and establishment of international domain in practice.

Expectations have been satisfied to a high extent in specializing the activities and development of courses and it has a promising future.

Regarding the entrance into international arena, as was mentioned before, infrastructures have been established; however, no notable success has been acquired so far. As internal market is saturating now, entrance into international arena is a vital issue considering ACECR potentials; it should be noted that time is the determinant factor.

In needs assessment, there is a gap compared to the program in both national and local levels.

Interaction with executive agencies is among the most important strategies which has attracted the managers' attention. It is noteworthy that, changes in government's policies in many years has influence much the success of ACECR programs. Therefore, membership in numerous committees and workgroups in provinces and at national level can guaranty the interests of ACECR.

Growth and innovation perspective

The most fundamental perspective among the mentioned ones is the growth and innovation perspective. Though managers try to consider this issue and understand that human resource is the most valuable wealth of ACECR, most activities related to human resource have a delay compared to the program which indicates insufficient attention of managers to employers of this institution.

Although there are gaps concerning the information wealth, they can be compensated by a new version.

Considering high importance of organizational wealth for managers, there is a gap in this domain in comparison with the program. Presently, a shift in generations is observed in ACECR; indeed, youths of the years 1979-80 who established ACECR and formed its values are currently being retired and their positions are provided to the next generation. Has the next generation been trained enough to maintain these values and are the experiences, opinions, and achievements of experienced individuals documented in the organization? Managers are responsible for transferring these knowledge and values from the antecedent generation to current generation; however, the managers' performance in this field has not been satisfactory from the researcher's point of view.

We have so far mentioned the general analysis of strategy in different perspectives of balanced score card model in ACECR. In following, we present some solutions for improvement of the current status.

Suggestions yielded from this study

1. More attention to welfare of staffs is a significant step to coordinate them with the organization's strategic program;

2. In addition to welfare of staffs, another factor which increases the staffs' commitment for executing the program is their participation in design of the program. General revision of the program with participation of staffs in middle and lower positions enhances the program's execution guaranty;

3. A relatively suitable control system exists for the program; however, it has not been considered to confirm the statistics provided by the units. So it is essential to reinforce the controlling system of the program for confirmation of the statistics' validity;

4. Another approach for reinforcement of this controlling system is to prepare a systematic and pre-determined monitoring plan to update the program;

5. Motivating the managers, other than those of central unit who have satisfactory participation, to better participate in strategic program of ACECR;

6. Making use of a foreigner expert consulting team during the organization's strategic management process;

7. Another factor which increases the commitment to program execution is causing motivation. These motivations may be financial or non-financial, such that the performance of each unit should be analyzed at the end of each year; the level of deviation from the program should be determined for each unit and the results should be reported. Also, staffs of the units with satisfactory performance should be appreciated; nevertheless, such a system does not exist at present;

8. Since most activities of ACECR are accompanied by marketing, implementation of a comprehensive marketing system in ACECR collection is essential. Certainly the establishment of such a system will alleviate the major problems of this institution in identification of markets, finding projects, needs assessment, etc. especially at international level. It should be mentioned that there are serious problems in most programs for recognition of opportunities and needs.

9. The present management system of human resource suffers from numerous weaknesses and even its most primitive components have not been executed. Revision of current status and establishment of a comprehensive system of human resource management will decrease the problems existing in the program in human wealth perspective.

Suggestions for improvement

1. Considering current conditions in the region, suitable opportunities exist for activity in Iraq and Afghanistan, even holding basic and primitive programs; however, this may encounter with

prevention of rivals, which should be taken into consideration. In general, strategy of ACECR for entrance into international arena should be totally revised due to change in political conditions of Iran in the world; otherwise, the present approach would not lead to successful outcomes.

2. In the perspective of organizational wealth which is of high significance for ACECR, it was mentioned that there is a major change in this organization, i.e. retirement of present managers and their replacement with young managers with different ideas and values. To transfer the values and experiences of previous generation to this generation, existence of a knowledge management system and its establishment in ACECR can play a vital role in such a transfer. Furthermore, by projects such as extraction of the knowledge of managers and key individuals, their valuable experiences can be documented. This documentation can even be presented in ACECR culture, since no published work exists so far; but as the managers believe, the most significant reason for success of ACECR has been following the ACECR culture.

Abstract: In the present rapidly changing world, a massive amount of raw data is generated, collected and organized in databases. This data contains lot of useful and important information which is hidden and not directly accessible. There is vital need for in-depth data analysis tools which can turn raw data into knowledge. This situation is known as “data rich but information poor”. It is very time consuming, slow and expensive to analyze and understand the huge volume of data manually specially when the data is in the form of text. Textual data need huge resources to preprocess it to make it ready for the data/text mining algorithms. In this paper we have proposed an effect preprocessing methodology for textual data which have produce quality data efficiently and reliably. [Dr. Muhammad Shahbaz, Dr. Syed Muhammad Ahsan, Maryam Shaheen, Muhammad Shaheen, Syed Athar Masood. An Effective Preprocessing Methodology for Textual Data Classification. Journal of American Science 2011;7(6):944-951]. (ISSN: 1545-1003). <http://www.americanscience.org>.

Keywords: Text Mining, Data Mining, Classification, Knowledge Discovery, Parsing, P-Tree

Introduction

The word data mining has many other synonyms like knowledge extraction, knowledge mining, data archaeology, data dredging and data pattern processing. Data mining is given the name from gold mining. As in gold mining people dig rocks to find gold, similarly analysts use data mining tools to find precious nuggets (knowledge) from raw data.

Data mining is the main step in the KDD process that consists of applying data analysis and discovery algorithms that, under acceptable computational efficiency imitations, produce a particular enumeration of patterns (or models) over the data [2].

The data mining phase of the KDD process basically relies on the algorithms that are useful in extracting and analyzing the patterns. Most of these methods are applied and extensively being used. Data mining step is iterative in nature as the techniques used are tried and tested many times until goal is achieved. The data mining algorithms belong to the machine learning, pattern recognition, statistics and artificial intelligence fields. Data mining algorithms consists of three components [1]:

- **Model Representation**

Mined patterns are represented by using some modeling language. The language should be selected very carefully so that correct model of data is formed otherwise it results in poor accuracy.

- **Model Evaluation**

Special quantitative measures (criteria) are defined to test a particular pattern against the

KDD goal. It shows how well a model meets its defined criteria.

- **Search**

Its main functionality is performing the optimization task of evaluation criteria.

Data Mining Methods

Data mining tasks can be divided into two groups by the kinds of pattern they discover: descriptive and predictive. Descriptive mining tasks deals with common properties of the data which are human understandable while predictive mining tasks involve the prediction of future values by making inference on current values of data.

Summarization and Visualization

Summarization methods give summaries of data. These methods describe subset of data in compact form like average, standard deviation, means etc. Visualization techniques provide graphical overview of data by which analysts can perceive data more easily that will be more helpful in data analysis. Examples include pie chart, bar chart, histograms, and multidimensional tables. More information can be studied through graphical form of data than to study texts and numerical form [2].

Classification

Classification is a way to divide data into groups which have already defined classes. Classification process is carried out in two steps: learning and classification. In learning phase, model is built by using pre-defined set of classes on data. Subset of data selected for learning purpose is called training data which is randomly selected during classification process. The learned model is then presented in the form of classification rules, decision trees, or

mathematical formulae. In the classification phase, the model which presented in some suitable form is then tested against some test data to estimate its accuracy. If accuracy is good enough then this model can be used for classification of future coming data whose class label is not known.

Regression

The process to model and analyze continuous values by using statistical methods is called regression. This technique is based on one independent variable and one or more dependent variables. Independent variable is that which is used to make prediction and dependent variable is the one which is to be predicted. Existing values are used to make prediction for future ones. The simplest form of regression is the linear regression in which data uses straight line model. CART (Classification and regression Trees) algorithm is mainly used for this purpose.

Clustering

Clustering is also a descriptive task which divides the data into groups which have no class information associated with them so that objects in the same clusters are more similar to each other than to the objects in other clusters. It is a form unsupervised learning in which classes is not defined at the start. Most common algorithms used in clustering are K-means and Kohonen feature maps. One major problem with clustering is to define the number of clusters in the beginning which can affect the accuracy.

Link Analysis

Link analysis helps in discovering the relationships and associations between the data values of the given dataset and represents these in the form of rules. These rules represent those values which frequently occur in the data set under consideration. It is also known as association rule mining. Link analysis technique is also descriptive in nature. Market-basket analysis is the most commonly used example of association analysis.

Association rules identified are written in the form $A \Rightarrow B$, where A is called antecedent and B is known as consequent. The most commonly used algorithms to find the association rules are Apriori Algorithm and FP-growth.

Outlier Detection

Outlier analysis or change detection tries to find those data values which show different behavior from the previous measured values. These are known as outliers. Some algorithms discard these as noise but in some cases where unusual happening events are of great importance, these are not thrown away. It can help in detecting the misuse of credit cards or telecommunication service. Visualization tools help a lot in detecting the outliers as human eye is very

efficient in noticing the unusual behavior or data inconsistencies, but this process remain effective with lower dimensionality as higher dimensions are difficult to perceive.

Text Mining

Textual data consists of raw data or free text which is easily understandable by human beings. The text words are in printed format or written material which can be displayed on a display screen. It is written in any of the natural languages which human beings use to communicate with each other. This kind of data is not readable and understandable by computers or machines. To make this unstructured data usable by computers, natural language algorithms are being applied on it to make it suitable for further processing.

Characteristics of Text Data

- **Large Textual Database**

In this "Information Age", most of the textual data of companies like reports, emails, web pages etc. is in electronic format. Most of the publications, books, related material are available and easily accessible through the internet.

- **High Dimensionality**

The textual data is considered to be as of sparse in nature. Each keyword is regarded as a separate dimension. This makes the data very complex to understand.

- **Unstructured Nature**

The data is in unstructured form which is not readable and understandable by machine. No specific data type and data structure is defined, the words of the text are considered as words only. It's been said that 85% data of the companies is in unstructured form [5].

- **Noisy Data**

The textual databases are noisy in nature as these contain a lot of grammatical and spelling errors. There is difference between the original text representation and short-hand words used like in SMS, chat, and e-mail [6].

Text Mining

Text mining is a step in the KDT (Knowledge Discovery in Text) process consisting of particular data mining and NLP algorithms that under some acceptable computational efficiency limitations produces a particular enumeration of patterns over a set of unstructured textual data [3].

KDT is same like KDD (knowledge Discovery in Databases) discussed in last chapter except that KDT deals with only textual databases. Similarly, text mining differs from data mining in the case that text

mining deals with only unstructured text while data mining is applied on structured databases often numerical in nature. KDT indicates the overall process of conversion of unstructured text into knowledge while text mining is the small step in the whole process of KDT which has the main purpose of extracting the useful patterns from the free text.

Text mining uses data mining, information retrieval and NLP techniques and algorithms to extract useful information hidden in the text. All these areas combined together according to the problem to form a text mining pipeline.

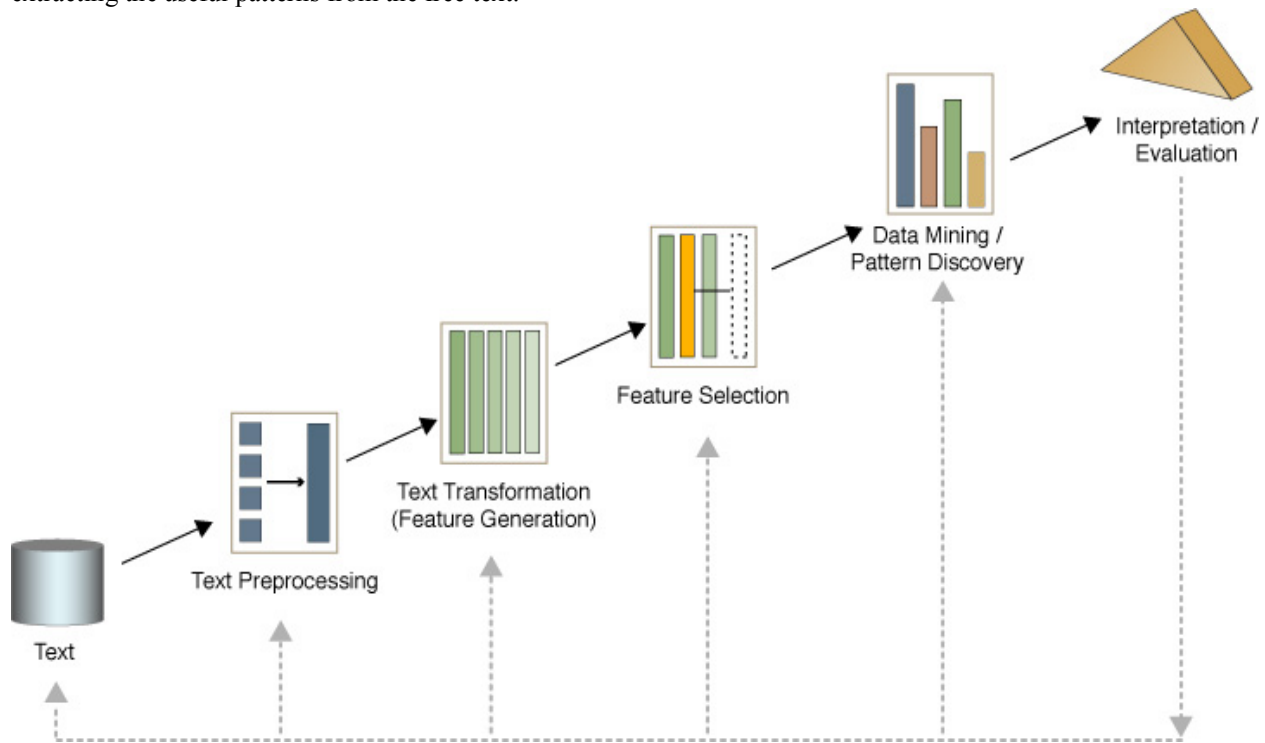

Figure 1. Text Mining Process [4]

According to Marti Hearst, “Text mining is the discovery by the computer of new, previously unknown information by automatically extracting information from different written resources” [7]. The most important thing is the bonding of the mined information together to form new piece of information or knowledge which can be investigated more by using the same usual algorithmic methods.

The limitations of text mining are: firstly, it is very difficult to write a program which can infer text data for a very long time, because with a passage of time new things are being added in the vocabulary. Secondly, sometimes novel information which has to be extracted from the text is not in mentioned in the textual data [7].

Text Mining Process

A text mining process is a multistep procedure which is shown in figure 1. It is an iterative method where the output of one stage becomes the input of the stage following it. The process which completes a text mining process consists of following stages [4]:

Text Preprocessing

The first step of text mining process is text preprocessing in which the document collection is analyzed syntactically or semantically. The meaning and grammatical structure of the language in which document collection is written is analyzed and recognized. The algorithms being applied here Part Of Speech tagging, Word Sense Disambiguation and Parsing.

Text Transformation

Text transformation deals with the feature generation part of the text analysis. The text document is considered as bag of words because the words and its occurrences are used to represent the document. The algorithms applied at this stage are stemming and stop word removal. Sometimes feature generation task is also included in the text preprocessing step of the text data mining.

Feature Selection

This stage consists of specialized techniques to select the fewer terms which can best represent the text collection. It will help out in reducing the large dimensions to small number. Feature selection

parameters can be of like information gain, chi square, mutual ratio etc. Only selected features are then kept to represent the document collection, the remaining ones are discarded.

Text/Data Mining

This is the part of process where the actual patterns are to be revealed from the textual data. At this stage the actual process of text mining or data mining is being applied on unstructured data. The interesting patterns are extracted from the textual data to convert it into valuable knowledge.

Result Evaluation

At the end the resulting features are then evaluated to check the accuracy of the applied algorithms. The knowledge is then also used to predict the future values of the data.

Peano-Count Trees Data Structure

P-Trees basically use vertical partitioning where data is divided into columns per bit rather than column per

attribute. If data stored in the columns is in particular sequence, following benefits can be achieved through this technology.

- Compression
- Hardware Optimization (AND operation)
- Efficient index implementation
- Only necessary data in memory

Basic P-trees

P-Trees resemble old data structures like Quad-Trees and HHcodes in the sense that these organize the data into quadrants. The idea behind this is, to divide the image into four quadrants recursively until single bits are left at leaf nodes and then count the number of ones in each quadrant, leads to the formation of P-trees. Each bit file of bSQ format is then converted into P-trees by following the recursive raster order. An 8x8 bSQ file and its P-tree is shown in the Figure 2

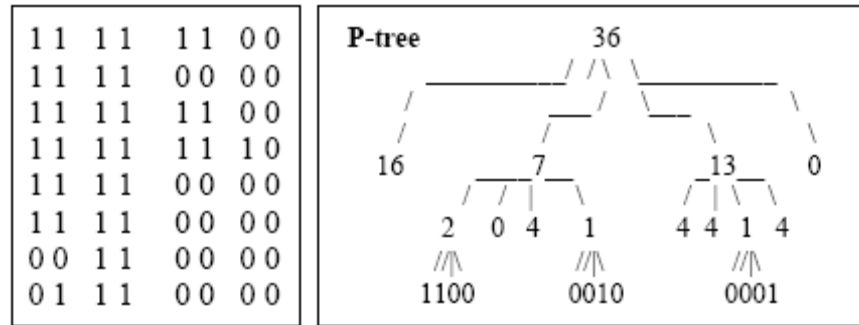

Figure 2. 8x8 bSQ File and its P-tree [8]

In the example shown above, 36 is the root count (number of one's) of whole image. This is labeled as level-0. 16, 7, 13 and 0 are the root counts of the level-1 quadrants traversed in Peano-order. 16 represent the number of ones in the first quadrant, 7 represent the number of ones in second quadrant, 13 is the root count of third quadrant while the fourth quadrant shows that there all zeros in it, number of ones are zero here. The first quadrant is composed of only 1-bit so it is known as pure-1 quadrant. Similarly if the quadrant is composed entirely of 0-bits then it is called pure-0 quadrant. As these are pure quadrants, there is no need for further branches. At last, each branch terminates i.e. leaf sequences are reached which are also pure as these consist of only one bit.

Considering the spatial data, basic P-trees are constructed for each bit position in each band. For n bands 8n basic P-trees are constructed assuming 8-bit values in bands. These basic P-trees are labeled as $P_{i,1}, P_{i,2}, P_{i,3}, \dots, P_{i,8}$ for all 8 bits for i^{th} band. The

basic P-trees are considered as “data-mining ready” and “lossless format” [8] for storing spatial data as it provide more information about data.

Figure 3. A 16-bit bSQ file converted into P-tree [9]

Value P-trees

A value P-tree ($P_{b,v}$) is basically the representation of value v at band b in the form of P-tree. Value v can be of any precision from 1-bit to 8-bit, so P-trees formed have value of more than one bit. Value P-trees can be constructed by combining the basic P-trees using the logical operations. For example, $P_{b,101}$ can be constructed by combining the basic P-trees as:

$$P_{b,101} = P_{b,1} \text{ AND } P'_{b,0} \text{ AND } P_{b,1}$$

Where $P_{b,101}$ gives the number of one's of band b bit 1 equal to 1, bit 2 equal to 0 and bit 3 equal to 1. Here AND operation do the pixel wise ANDing of the bits.

Tuple P-trees

The value P-trees for any combination, are then combined to form tuple P-tree. It is constructed for any value combination (v_1, v_2, \dots, v_n) of band I , shown as:

$$P(v_1, v_2, \dots, v_n) = P_{1,v_1} \text{ AND } P_{2,v_2} \text{ AND } \dots \text{ AND } P_{n,v_n}$$

It gives quadrant wise count of occurrences.

Interval P-trees

The P-Trees created by the values lying in specific intervals $[v_1, v_2]$ of band i are known as interval P-trees. These are shown as follows:

$$P(v_1, v_2) = \text{OR } P(v), \text{ for all } v \text{ in } [v_1, v_2]$$

P-Tree Variations

Peano Mask Tree (PM-tree) is a variation of P-Tree in which masks are considered rather than the counts by using the 3-value logic for representation of pure-1, pure-0 and mixed quadrants. Pure-1 is represented by 1, pure-0 by 0 and mixed quadrant is denoted by m .

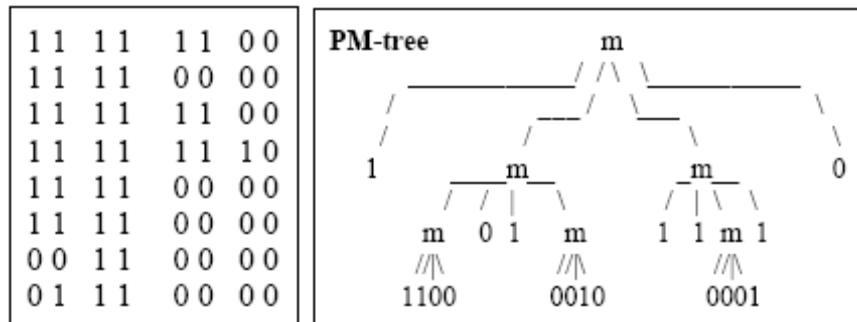

Figure 4. PM-Tree [8]

P1-tree uses 1 to represent pure-1 quadrant while 0 is used to represent pure-0 quadrant.

In P0-tree, 1 is used to represent pure-0 quadrant and 0 represents the other quadrants.

In non-pure-0-tree, 1 represents non-pure-0 quadrant which indicates pure-1 quadrant and mixed quadrant and 0 to represent pure-0 quadrant. Non-pure-1-tree is the vice versa of non-pure-0-tree.

Figure 5. P1-tree and P0-tree [8]

Operations of P-Trees

AND

AND is the basic operation performed on the bits represented in the P-Tree form. It is the most widely

used operation to check the equality of bit sequences with constant. AND operation can be performed in different ways but most important ones are level wise ANDing and Pure-1 path ANDing.

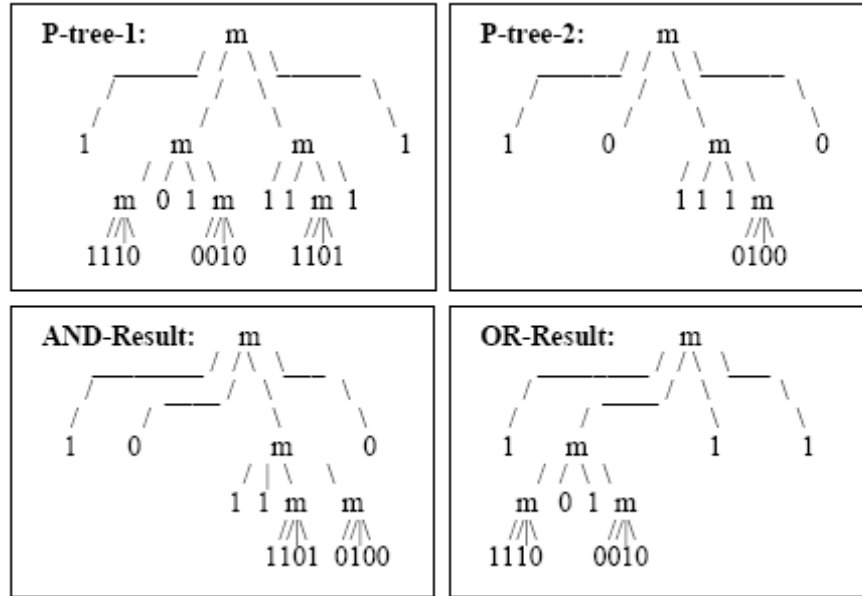

Figure 6. P-Tree AND and OR Operations [8]

In level-wise ANDing [8], rules are being specified to perform the AND operation. Operands are given in the P-tree form with mentioned roots. These rules can be of the form: ANDing of pure-1 P-tree with any P-tree give result in the form of P-tree showing second operand. Pure-0 P-tree will be generated when a pure-0 P-tree is ANDed with any P-tree.

In pure-1 path ANDING process [8], only basic P-trees are stored then the value and tuple P-trees are generated when these are needed. Here assumption is that P-trees use the depth first scheme for the paths to the pure-1 quadrant. Quadrants are identified by hierarchical scheme, that an id number is being attached to each quadrant at each level. These numbers are 0 for upper-left quadrant, 1 for upper-right quadrant, 2 for lower-left quadrant and 3 for lower-right quadrant. The same quadrant numbers are being tagged on at each level.

For an 8x8 image, the pixel at (3,6) has values (011, 110), so quadarant id is calculated as by combining two bits such as (01.11.10)=1.3.2. The quadrant can also be written as 132 instead of 1.3.2 for easiness as shown in the figure 6.

In this algorithm, the paths to the pure-1 quadrant are considered to be in the depth-first sequence. In this scheme, the paths are being represented in the form of quadrants which obey Peano-ordering. Peano Quadrant is the process of identifying the quadrant id as shown above. So

ANDing is done by scanning the operands and then output the pure-1 paths which are matched.

In the example shown in the below figure, two mask P-trees for two operands are given. The ANDing result of these two P-trees is shown in a form of P-tree. Considering the depth-first order the first value is 0 which means it is 0 quadrants. Second quadrant is mixed, so it will first retrieve the leaf node of this quadrant which has one value such as: 100, 101 and 102. Similarly, it will identify the other quadrants and then AND the values.

0	100	101	11
	102	103	
	12		13
2	3		

Figure 13. Quadrant Numbers [8]

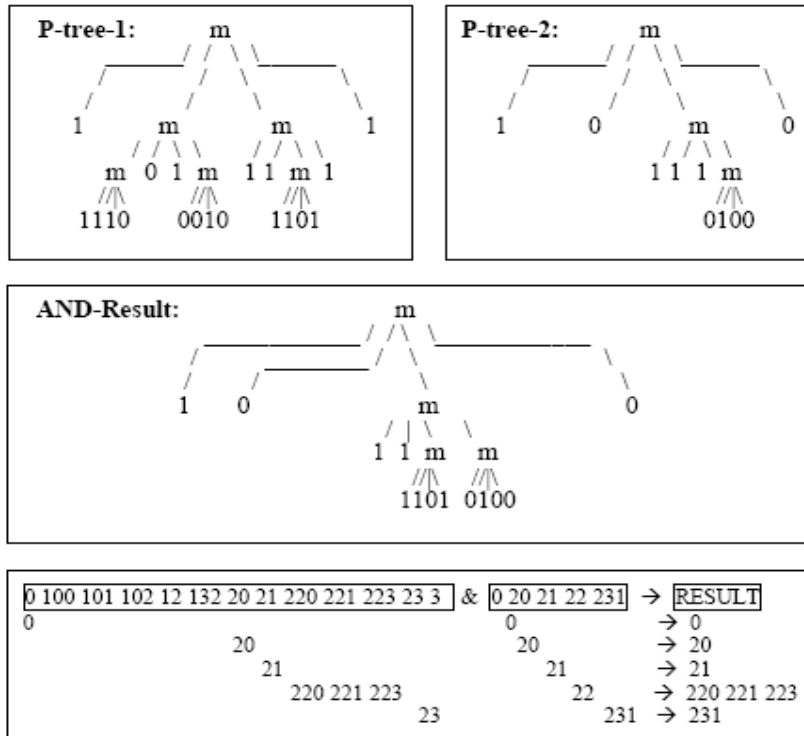

Figure 8. ANDing of PM-trees using Pure-1 Path [8]

OR

OR operation can be implemented in the similar way as the AND operation is being implemented. Most of the times it is implemented as ANDing the first operand with the complement of second one.

Every P-tree shows the natural property of complement. The complement process is very simple; it just takes basic P-tree and then complements the counts at each level (this is done by subtracting the counts from pure-1 counts at that level). Complement gives the number of zeros for each quadrant in a P-tree.

Complement

Figure 9. Complement Operation of P-Tree [8]

Count

Count operation basically counts the number of ones in each quadrant for a given P-tree in Peano order. This helps in identifying the number of bit sequences that can satisfy a particular condition. Counting algorithm can be implemented as a shift operation on integer taking one bit at a time OR it can be implemented by counting the occurrences of one's

directly from the look up table taking multiple bits at a time.

Proposed Solution

In this chapter, a solution is being given to the problem that document should be represented in some structured form so that data mining algorithms can be directly applied to it. This proposed methodology discussed below, converts the

document into ready form after applying some necessary steps.

Preprocessing step:

After removing the stop words (most common words like the, a, an, the, of, or and so on) and applying stemming (truncating the words to their common root such as “printing”, “prints”, “printed” to the root “print”), the important terms from each document in the collection are collected, this can best describe the documents in the whole collection.

Document Model:

Each document in the collection is now represented as a vector by using the vector space model. Terms are the dimensions and documents are the points in the space. This whole document-term collection is now represented as term-document matrix.

The most common used method to represent the relation between terms and documents is tf-idf weighting scheme, which combines the local and global weights together. It discriminates the term from the collection and gives importance to those terms which mostly occur in a document and less occurring in the whole document collection.

$$\text{weight}_{ij} = \text{freq}_{ij} * \log \left(\frac{N}{\text{docf}_i} \right)$$

Where N= total number of documents in collection

docf_i= number of documents in which term i occur

freq_{ij}= frequency of term i in document j

This is most widely used weighting scheme to discriminate the term from the document collection point of view.

Tf-ITF measurement is proposed for the term-document data weights, which gives importance to the terms occurring frequently in the document and document is more specific about the topic. It is a local weighting scheme only as it considers the document in consideration not the whole collection of documents. ITF measurement (already proposed) gives high weights to the documents which contain less terms i.e., these documents are more specific about the topics; if documents contain more terms then the document is generic in nature.

$$tf - ITF = tf \times \log \left(\frac{M}{\text{doc}_{ti}} \right)$$

Where M= total number of terms extracted from the document collection

doc_{ti}=number of terms in a particular document

This weighting scheme shows document richness (relative information about the terms in a document) information. When multiplied with term frequency it gives high weight to those terms which are frequent

in the topic specific document. ITF is same for one document representing its length and richness. When term frequency factor is being added in it, then this weighting scheme shows the high weighting for the terms occurring mostly in the document scenario and low weights to the terms occurring less frequently.

Conclusion

This weighting scheme can be used for the shortening purpose of documents as only frequently occurring terms are being extracted from each document. These terms show the document main theme and topic. These frequently occurring terms or important ones are being used to represent the documents in a convenient and useful manner. These important terms in each document can represent some relationships between the documents which is helpful in further analysis.

This is more useful in knowledge extraction part of the whole mining process. As essential features of a text document are extracted by the pre-processing technique and are represented by the form a model. This model will further analyzed to mine the information being hidden in the data like relationships between the documents, importance of each term in particular document scenario, document main theme and so on. This will be done the future analysts.

Abstract: From 1990s onwards, biological and chemical research in both the public and private sectors throughout the world has been transformed into industrial scale by the creation of databases with large amounts of high-quality, freely available DNA sequence data. These databases have not only enabled the comprehensive cataloging of human genes but have also accelerated the discovery of new forms of cellular regulation rendering biology and chemistry a discovery science thus providing the basis for novel experimental approaches. We however feel that the potential opportunities, accessibility and power of open source science and publicly available data have not transformed into gains and significant impact on scientific discovery. In this paper we have identified many issues with the existing conventional chemical biology and molecular biology databases and propose the development of ChemBank v3.

[Syed Ahsan, Muhammad Shahbaz, Syed Athar Masood. Creation of Next generation Open Source Science Databases. Journal of American Science 2011;7(6):952-955]. (ISSN: 1545-1003). <http://www.americanscience.org>.

Keywords: biological research, open source science, databases

1. Introduction

Life Science research in post-genomic era is integrative, collaborative and mainly insilico. Therefore, in our opinion the life science research community should be provided with an integrated, transparent access to data and analytical tools of experimentation. In this perspective the Broad Institute's mission is to develop powerful new tools for genomic medicine and to make those tools available to the world. Currently, researchers outside of the Broad cannot easily access the wealth of information being generated by the chemical biology platform within the Broad. Although this data is all publicly available through the PubChem database, PubChem does not provide users with sufficient context to be able to fully interpret the data. Therefore, it is essential that we create a new database to provide this additional context and information. Without this, we are making data public without making it useful.

The Chemical Biology Platform at the Broad developed the original ChemBank and the most recent updated version is ChemBank v2. ChemBank has been created to provide a platform for sharing data on assays and compounds in what can be termed as "open source" science. ChemBank v2, although pioneering in sharing chemical and biological data to the community at large, is limited in terms of the details and underlying experimental design. As a user you only get to see the result of the experiment and not how we got to these results. The information on the compounds is rather limited with no details on how to synthesize them. Similarly, in the absence of

experimental and protocol design information users of the data are rather limited in terms of reproducing the experiment and extend science. As a result, researchers outside of the Broad cannot easily access the wealth of information being generated by the chemical biology platform within the Broad. Although this data is also publicly available through the PubChem database, PubChem does not provide users with sufficient context to be able to fully interpret the data. Therefore, it is essential that we create a new version of ChemBank database i.e., ChemBank V3, to provide this additional context and information. Without this, we are making data public without making it useful.

2. Next Generation of Chemical Database

In the section above, we discussed the limitations of existing chemical database at Broad. In our opinion, these limitations need to be removed on priority basis to enable chemical biology and drug discovery as an integrative, collaborative and explorative science. To achieve this objective, we are proposing the development of ChemBank v3. This database would contain information on small molecules contained in the Broad Institute screening collections along with details of the assays performed on those molecules and any results. Where possible, the database would link to other external databases containing related information, such as ChemSpider and PubChem. Such a database would be transformative in enabling effective use of this research data and in establishing new standards for quality and transparency in public databases. This

proposal articulates about the scope and background, the current state of the art, the objectives & methodology along with milestones and other consideration for the project.

We fully expect that this new version of ChemBank will be used as a model for other new databases and for improvements to PubChem and other existing databases. Our goal with ChemBank is not to supplant these other databases, but to provide an example that it is possible to provide context rich data which they may emulate.

Development of ChemBank V3 will enable us to create a chemical sample repository that links physical compound samples used throughout the probe development process, including primary screening, follow-up chemistry, target identification, and Connectivity Map profiling. Probe-development projects involve ongoing chemical syntheses, including multiple independent syntheses of the same compound. To fully support probe development, *ChemBank* v3 must associate biological data with the physical sample used, not just the compound structure, and with sample-specific analytical chemistry information. *ChemBank* v2, which is the current public sharing site, (and PubChem) associates most information only at the level of abstract structure, not physical sample. We will release chemical sample repository as the first component of *ChemBank* v3 that includes analytical chemistry results on the quality of compounds, and synthesis pathway information when available. This repository will link out to PubChem and ChemSpider to make it simpler to use these resources for probe development. At the outset, the repository will contain both public and DSA versions, as not all samples will be publicly disclosed compounds.

ChemBank v3 will also provide a searchable repository of small molecule assays. The screening center captures all biological assays in an electronic lab notebook. We will provide a read-only version of the public portions of these notebooks with both browse and search capability that will any user to quickly locate assays or protocols of interest. Users can then link from these assays to the small molecule results generated from them.

There are several major challenges associated with this project. There are technical challenges associated with the required integrations. The new ChemBank site must be integrated with the PubChem and ChemSpider sites externally, and additionally the back end must integrate with several commercial

products licensed to the Broad Institute, including the CambridgeSoft eNotebook Data Warehouse and the Dotmatics Browser.

Additionally, there is a user interface design challenge since the goal is to make the site approachable for those who are not familiar with the experiments it contains. Our internal interfaces are designed for expert users and so work very differently.

3. Conclusion

The development of ChemBank v3 is a research intensive activity. In our opinion, this will translate into at least two research papers in reputed international journals. Also as Life Science research in post-genomic era is integrative, collaborative and mainly in-silico, the development of ChemBank V3 will help the scientific and research community achieve the following objectives and advantages. The advantages mentioned below once achieved will help the design and creation of other scientific databases. We feel that as modern day science is data intensive, lessons learned in one scientific domain can be mapped to other scientific domains.

The following are the objectives that will be achieved by development of ChemBank v3:

- i) Support dry lab (In-silico) experiments
- ii) Avoid reenactment of experiments
- iii) Achieve interoperability of data and applications
- iv) Enable reusability of workflows and results
- v) Share results through transparent exchange of data
- vi) Provide inter-application communication
- vii) Create, store and access experimentation procedure/methodology i.e workflows as the workflows are considered the research results in the life science research.
- viii) Support the autonomous development and collaborative Research.
- ix) Most of the genomics databanks and tools do not yet provide enough standardized computer-readable metadata to facilitate the workflow automation and integration. ChemBank v3 will ease the bottleneck of domain-specific knowledge expert needed to interpret what the data actually represents before using it in the integration experiments.

Abstract: The data mining has emerged as a powerful tool to extract knowledge from huge databases. Researchers have introduced several machine learning algorithms to explore the databases to discover information, hidden patterns, and rules from the data which were not known at the data recording time. Due to the remarkable developments in the storage capacities, processing and powerful algorithmic tools, practitioners are developing new and improved algorithms and techniques in several areas of data mining to discover the rules and relationship among the attributes in simple and complex higher dimensional databases. Furthermore data mining has its implementation in large variety of areas ranging from banking to marketing, engineering to bioinformatics and from investment to risk analysis and fraud detection. Practitioners are analyzing and implementing the techniques of artificial neural networks for classification and regression problems because of accuracy, efficiency. The aim of his short research project is to develop a way of identifying the clusters in high dimensional data as well as redundant dimensions which can create a noise in identifying the clusters in high dimensional data. Techniques used in this project utilizes the strength of the projections of the data points along the dimensions to identify the intensity of projection along each dimension in order to find cluster and redundant dimension in high dimensional data. Introduction

In numerous scientific settings, engineering processes, and business applications ranging from experimental sensor data and process control data to telecommunication traffic observation and financial transaction monitoring, huge amounts of high-dimensional measurement data are produced and stored. Whereas sensor equipments as well as big storage devices are getting cheaper day by day, data analysis tools and techniques wrap behind. Clustering methods are common solutions to unsupervised learning problems where neither any expert knowledge nor some helpful annotation for the data is available. In general, clustering groups the data objects in a way that similar objects get together in clusters whereas objects from different clusters are of high dissimilarity. However it is observed that clustering disclose almost no structure even it is known there must be groups of similar objects. In many cases, the reason is that the cluster structure is stimulated by some subsets of the space's dimensions only, and the many additional dimensions contribute nothing other than making noise in the data that hinder the discovery of the clusters within that data. As a solution to this problem, clustering algorithms are applied to the relevant subspaces only.

Immediately, the new question is how to determine the relevant subspaces among the dimensions of the full space. Being faced with the power set of the set of dimensions a brute force trial of all subsets is infeasible due to their exponential number with respect to the original dimensionality.

In high dimensional data, as dimensions are increasing, the visualization and representation of the data becomes more difficult and sometimes increase in the dimensions can create a bottleneck. More dimensions mean more visualization or representation problems in the data. As the dimensions are increased, the data within those dimensions seems dispersing towards the corners / dimensions. Subspace clustering solves this problem by identifying both problems in parallel. It solves the problem of relevant subspaces which can be marked as redundant in high dimensional data. It also solves the problem of finding the cluster structures within that dataset which become apparent in these subspaces. Subspace clustering is an extension to the traditional clustering which automatically finds the clusters present in the subspace of high dimensional data space that allows better clustering the data points than the original space and it works even when the *curse of dimensionality* occurs. The most of the

clustering algorithms have been designed to discover clusters in full dimensional space so they are not effective in identifying the clusters that exists within subspace of the original data space. The most of the clustering algorithms produces clustering results based on the order in which the input records were processed [2].

Subspace clustering can identify the different cluster within subspaces which exists in the huge amount of sales data and through it we can find which of the different attributes are related. This can be useful in promoting the sales and in planning the inventory levels of different products. It can be used for finding the subspace clusters in spatial databases and some useful decisions can be taken based on the subspace clusters identified [1, 2]. The technique used here for indentifying the redundant dimensions which are creating noise in the data in order to indentifying the clusters consist of drawing or plotting the data points in all dimensions. At second step the projection of all data points along each dimension are plotted. At the third step the unions of projections along each dimension are plotted using all possible combinations among all number of dimensions and finally the union of all projection along all dimensions and analyzed, it will show the contribution of each dimension in indentifying the cluster which will be represented by the weight of projection. If any of the given dimension is contributing very less in order to building the weight of projection, that dimension can be considered as redundant, which means this dimension is not so important to identify the clusters in given data. The details of this strategy will be covered in later chapters.

Subspace Clustering

Subspace clustering is a newer form of clustering which can find different clusters in subspaces within a dataset. Often in high dimensional data, many dimensions can be *redundant* and can create a noisy data for existing clusters. “Features selection eliminates the redundant and unrelated dimensions by analyzing the whole dataset. Subspace clustering algorithms searches for *relevant dimensions* allowing them to find clusters those exist in multiple overlapping dimensions. This is a particularly important challenge with high dimensional data where the *curse of dimensionality* occurs [3, 4]”.

What is subspace clustering?

Automatically identifying clusters present in the subspace of a high dimensional data space that allows better clustering of the data points than the original space. Cluster analysis exposes the groups or clusters of similar groups. “Objects are normally shown as point in multidimensional space. Similarity between objects is often determined by distance

measures over the various dimensions in dataset. Changes to existing algorithms are essential to keep up the cluster quality and speed since datasets have become larger and more varied [4]”.

Conventional clustering algorithm gives importance to all dimensions to learn about each object. In high dimensional data, often more dimensions are unimportant and can be considered as redundant. These irrelevant & redundant dimensions can confuse the clustering algorithms by hiding clustering in noisy data. In very high dimensions it is common for all of the objects in a dataset to be nearly equidistant from each other, completely masking the clusters. Feature selection methods have been working somewhat successfully to improve cluster quality. These algorithms find a subset of dimensions on which to perform clustering by removing irrelevant and redundant dimensions. Unlike feature selection methods which examine the dataset as a whole, subspace clustering algorithms localize their search and are able to uncover clusters that exist in multiple, possibly overlapping subspaces [5, 6].

“Another thing with which clustering algorithms fight is the *curse of dimensionality* [6]”. As the number of dimensions in a dataset increases, distance measures become increasingly worthless. Additional dimensions spread out the points until, in very high dimensions; they are almost equidistant from each other. Figure 4.1 illustrates how additional dimensions spread out the points in a sample dataset. The dataset contains 20 points arbitrarily placed between 0 and 2 in each of three dimensions. Figure 4.1(a) shows the data projected on one axis. The points are close together and are about half of them in a one unit sized area [6]. Figure 4.1(b) shows the same data in extended form into the second dimension. By adding another dimension, points are spread out along another axis, pulling them further apart. Now only about a quarter of the points fall into a unit sized area. In Figure 4.1(c) a third dimension is added which spreads the data further apart. A one unit sized bin now holds only about one eighth of the points. If we continue to add dimensions, the points will continue to spread out until they are all almost equally far apart and distance is no longer very important. The problem is made worse when objects are related in different ways in different subsets of dimensions [6]. It is this type of relationship that subspace clustering algorithms seek to uncover. In order to find such clusters, the irrelevant features must be removed to allow the clustering algorithm to focus on only the relevant dimensions. Clusters found in lower dimensional space also tend to be more easily interpretable, allowing the user to better direct further study [6].

Subspace clustering is also more general than feature selection in that each subspace is local to each cluster, instead of global to everyone. It also helps to get smaller descriptions of the clusters found since clusters are defined on fewer dimensions than the original number of dimensions. An example of subspace clustering can be in bioinformatics with DNA micro array data. One population of cells in a micro array experiment may be similar to another because they both produce chlorophyll, and thus be clustered together based on the expression levels of a certain set of genes related to chlorophyll. However,

another population might be similar because the cells are regulated by the circadian clock mechanisms of the organism. In this case, they would be clustered on a different set of genes. These two relationships represent clusters in two distinct subsets of genes. These datasets present new challenges and goals for unsupervised learning. Subspace clustering algorithms are one answer to those challenges. They excel in situations like those described above, where objects are related in multiple, different ways.

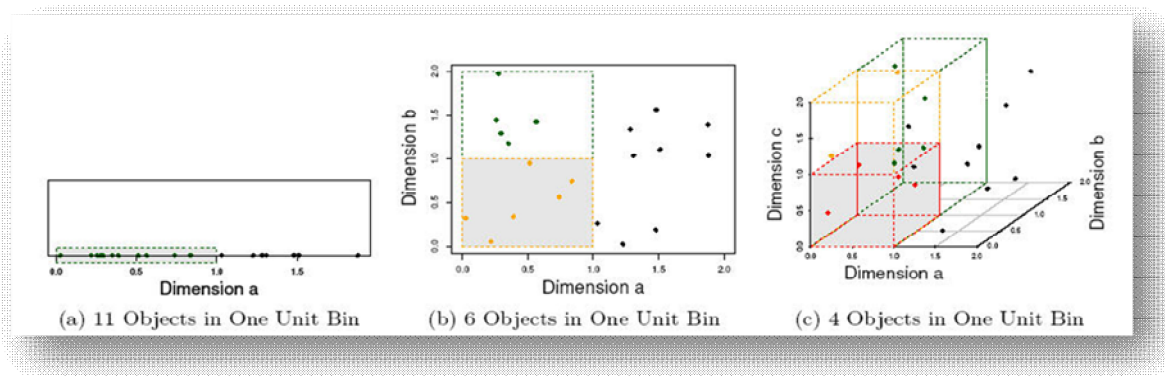

Figure 1. Dimension

Why subspace clustering?

Clustering is a great data exploring methodology which is able to identify previously unknown patterns in data. Subspace clustering is an extension of conventional clustering, based on the observation that different clusters (groups of data points) may exist in different subspaces within a given dataset. This point is particularly important with respect to high dimensional data where the curse of dimensionality can occur and can reduce the worth of the results. Subspace clustering is important due to following points.

- Most of the clustering algorithms have been designed to identify clusters in the full dimensional space so they are not effective in identifying clusters that exist in subspaces of the original data space [2].
- Many times the data records contain some missing objects. Such missing objects are normally replaced with objects taken from given distribution [2].

The clustering results formed by most of the clustering algorithms rely a lot on the order in which input records are processed [2, 8].

Dimension Projection Theory

In this section a theory of dimension projection is described. Just for an example for understanding, only three dimensions are considered

at first. In the first step, different data points are taken as input in which it is known that two clusters exist and is visible in all three dimensions and it is assumed that data is normalized in all of dimensions. The third cluster is visible in 2 dimensions but not visible in third dimension. For convenience the coordinates of all axis or dimensions are normalized.[7] The input data for the given example is described in the Table 1. The Table 2 shows the weights of the coordinates along all of the dimensions. Weights are calculated in such a way that the number of points are counted along each dimension on each and every coordinate and then total count becomes the weight of the coordinate along that dimension. Like Table 2 shows that the coordinate 5 (5th index along X-Axis) has 2 points so its intensity of weight is 2. The input data belongs to the three dimensions. There are three known clusters exist in the data. The two of them are visible in all three dimensions (Cluster 1 and Cluster 2). But the third cluster (Cluster 3) is visible only in two dimensions (X and Y-Axis) and is dispersed in third dimension (Z-Axis) and is not clearly visible in this dimension.

Drawing the points in 3 dimensional space XYZ plane will look something like as showing in Figure 2. The points in XY, YZ and XZ planes are also shown in Figure 3, Figure 4 and Figure 5 respectively. The Figure 3 which is showing points in

XY plane shows that three clusters exist but Figure 4 and Figure 5 are showing that there are two clusters only and remaining data points are scattered along Z-Axis which are not forming any cluster.

The shaded area in blue color is representing the projection of data points along X-Axis, the shaded area in the brown color is representing the projection of data points along Y-Axis and the shaded area in the red color is representing the projections of the data points along Z-Axis. The height of the shaded area shows the weight of the projection at that specific coordinate along that dimension. If the data is being visualized in three dimensions then it is observed that there are only two clusters present in the data as shown in Figure 2. The Figure 6 is also showing the overlapping of projections along X and Y-Axis but Z-Axis is has

very less overlapping of projections of data points. The existence of more clusters needs to be checked since more clusters might be present but not visible due to the presence of some dimension(s). Dimensions will be removed one by one and then data will be visualized for having more clusters and process will end up until data is visualized by removing all dimensions for all possible combinations and the numbers of clusters are also stored in some data structure to analyze later. The visualization is assumed in this project as an automatic process of finding the number of clusters in that given dimension. If one dimension is removed which is X-Axis in this case then the projections of the data points along YZ dimensions as follows.

Table 1. Intensity of weight

Cluster 1			Cluster 2			Cluster 3		
X	Y	Z	X	Y	Z	X	Y	Z
5	21	29	19	5	4	13	18	4
5	23	27	19	7	2	13	19	1
6	21	28	19	9	1	14	16	16
6	22	28	20	6	3	14	17	30
6	24	26	20	8	3	14	18	25
7	20	30	21	5	4	14	20	10
7	21	27	21	7	4	15	17	27
7	23	28	21	8	2	15	19	12
8	21	30	21	9	1			
8	23	29	22	6	3			
8	24	28	22	8	3			
9	22	26						
9	24	26						

Table 2. Projection

X – Projection		Y – Projection		Z – Projection	
Coordinate	Weight	Coordinate	Weight	Coordinate	Weight
5	2	5	2	1	3
6	3	6	2	2	2
7	3	7	2	3	4
8	3	8	3	4	4
9	2	9	2	10	1
13	2	16	1	12	1
14	4	17	2	16	1
15	2	18	2	25	1
19	3	19	2	26	3
20	2	20	2	27	3
21	4	21	4	28	4
22	2	22	2	29	2
		23	3	30	3

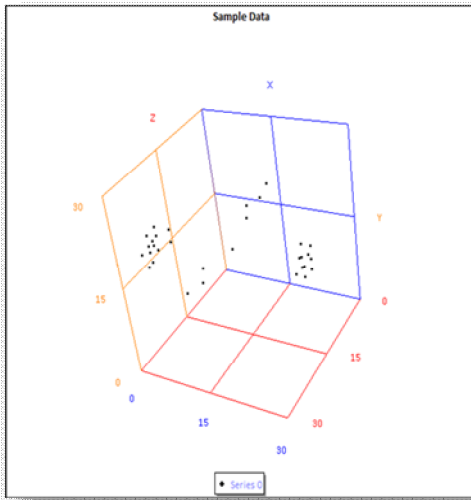

Figure 2

Figure 4

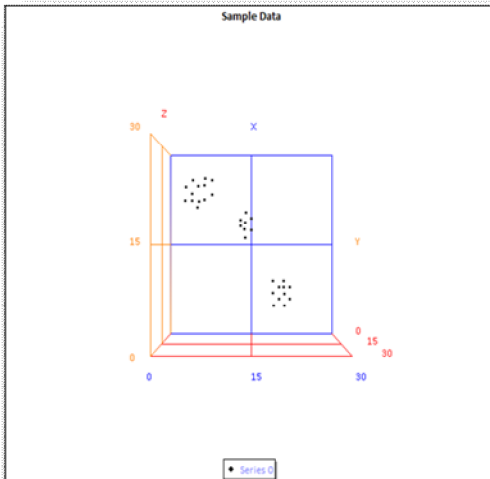

Figure 3

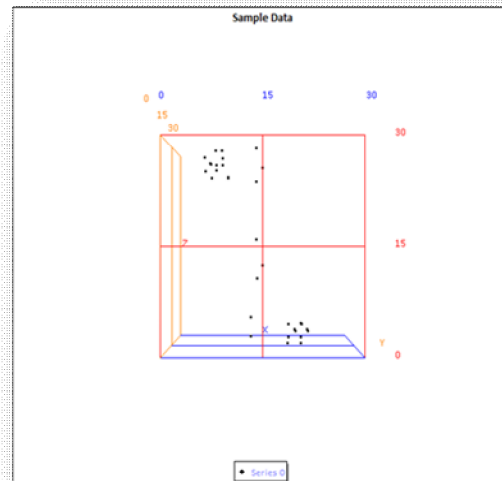

Figure 5

If the projections of data points are drawn along each dimension (in this case X-Axis, Y-Axis and Z-Axis) then accumulative projections of data points will be shown as in Figure 6.

Figure 6

Figure 7

The Figure 7 shows that there is no overlapping of projection of data points when X-Axis is removed but only single point is overlapping which is at 16th coordinate. So removing X-Axis might not be that effective in identifying more clusters in the

data since Figure 4 is also showing the two clusters. Now if another dimension which is Y-Axis is removed to check for more clusters by visualizing the data then the projections of data points along XZ dimensions will be as follows.

Figure 8

Figure 9

The above Figure 8 is showing that there is no projection overlapping exists by removing the Y-Axis and then plotting the projections of data points. Figure 5 is also plots the data points along XY dimensions and showing the existence of only two clusters. So removing Y-Axis is also not contributing in finding the more clusters in the given dataset. If we remove another single dimension which is Z-Axis and visualize the data, projections of the given data points will be shown as follows.

The Figure 9 is showing that that projection overlapping of the data points along XY dimension is larger than previous figures and most of the points

are overlapping. If data is visualized in these two dimensions as in Figure 3, it is shown that another cluster becomes visible which was not present previously. So after removing the Z-Axis, another cluster becomes visible so removing Z-Axis is contributing a lot in finding more clusters in the given dataset.

The procedure doesn't stops here. Now combinations of the dimensions are going to be removed to check further existence of clusters. If the X-Axis and Y-Axis are removed then the projection of data points along Z-Axis will be drawn as follows in Figure 10.

Figure 10

The Figure 10 is showing that data points are mostly scattered along Z-Axis and mostly not adjacent to each other. Visualizing the data in only Z-Axis is not yielding more clusters so this dimension is not so important and removing X-Axis and Y-Axis

might not contribute in cluster identification. Now if another combination of dimensions which is X-Axis and Z-Axis is removed and projection of data points are drawn along Y-Axis then figure will be something like below.

Figure 11

Figure 11 is showing the solid segment of projections which is representing the presence of clusters when data is visualized along Y-Axis only so this dimensions can be considered important in cluster identification. Finally if we remove Y-Axis and Z-Axis and projection are drawn only along X-Axis then it will be look like below in Figure 12.

In Figure 12, it is clear that along X-Axis projections of data points have more weight and data points are more adjacent and hence more chance of existence of clusters. If data is visualized along X-Axis only then it is clear that there are three clusters exist so this is also an important dimension in fining the clusters in the given data set. From the above

analysis it is clear that the Z-Axis is the only dimension which seems redundant and can be removed to discover more clusters available in the given dataset. In original data there were only two clusters but by removing one dimension one more cluster is found and adding Z-Axis dimension in the data is causing to create a noise in the data and hindering the clusters identification. This procedure was used for three dimension data but it can be used as it is for n-dimensional data as well and the projection drawn in this procedure also helps to find out number of clusters within the data with respect to all dimensions.

Figure 12

Algorithm

The above technique can be written in as an algorithm form.

1. Normalize the dimensions so that all dimensions should have same coordinates limit.
2. Generate the accumulative union of all the projections taken in all dimensions in such a way that weights of the final output projection on each coordinate will show the sum of all total number of data points at coordinate.
3. Visualize the data and identity number of clusters in the presence of all dimensions and store them in some data structure (visualization is assumed as an automatic process in this project)
4. Remove the dimensions one by one and identify the number of clusters available after removal and store them in data structure.
5. Remove all possible combination of dimensions which will 2^n and identify the number of clusters after removal store them in data structure.
6. Analyze the data structure with respect to the dimension combination and mark that

dimension as redundant which has less number of clusters in its presence.

This algorithm is efficient for less number of dimensions. As long as the dimensions are increased in the data, the algorithm efficient will become poor. Visualization of the data is also the beyond of the scope of this project but implantation of the algorithm is based on this idea.

Conclusion

In high dimensional data there can be number of clusters exists and there are different techniques or methodologies introduced to identify them with respect to different dimension and in that techniques sometimes it is figured out that some of the dimensions might not be so important in identifying cluster because of the dispersed data in that dimension and creating a noise in the data for indentifying clusters. The above technique uses the Projection of data points along each dimension to determine the weight or intensity of the data points along each dimension and visualization process to identify the number of cluster present in the data along that particular dimension. Weight is calculated

by counting the number of data points along that dimension. By removing the dimensions one by one and then all possible combinations of dimensions and then visualizing the data, it makes clear that which dimension is less important in order to find out the clusters in given subspace. The algorithm written has limitations of performance as it can work well with less number. of dimension and will become slow in high dimensions. Visualization process is considered as an automatic procedure which will return number of clusters given in the dataset. At the end the dimension which can be redundant can be removed which is creating noise and has less contribution in cluster identification in high dimensional data.

Competence of Nurses' Managers in Different Work Environment at Assiut University Hospitals

¹Kawther Abd El-Motagally Fadel, ²Samah Mohamed Abdalah, ²Fatma Rushdy Mohamed and ²Eman kamel hossny

¹Faculty of Medicine-Assiut University, ²Faculty of Nursing- Assiut University, Egypt

Abstract: Background: Healthcare providers are increasingly inclined to question the quality and efficacy of the care they provide. Nurse competence plays an important role in guaranteeing the quality of nursing interventions and outcomes. It is claimed that a key responsibility of nurse administrators is to ensure staff nurse competence. Nurses should maintain and demonstrate competence throughout their professional career. Nurse Managers have to continuously assess safe patient care. Aim of the Study: to assess competence of nurses' managers at different work environment at Assiut University Hospitals, and compare nurse's competence at different work environments at Assiut University Hospitals. Subject and Methods: the present study is descriptive, was conducted in all units of Assiut University Hospitals. It included all nurses' managers who are working in different departments at the time of the study. A personal interview questionnaire sheet which consist of two parts: ¹st Personal characteristics data which include name, age, department, marital status, educational level, position, years of experience and years of experience of the present position (head nurse, supervisor, assistant director, director of nursing), ²nd Nurse Competence Scale (NCS) was consisted of seventy three items structured in seven competence categories: helping role (seven items), teaching- coaching (sixteen items), diagnostic functions (seven items), managing situations (eight items), therapeutic interventions (ten items), ensuring quality (six items) and work role competences (nineteen items). The Scoring System was four-point scale (0 = not applicable in my work, 1 = very seldom, 2 = occasionally and 3 = very often in my work). The levels of competence are measured with a Visual Analogue Scale (VAS 0-100 mm), which the total score of the VAS with 0 meaning a very low level of competence, 1-30 mild level of competence, 31-60 good level of competence, 61-99 excellent level of competence and 100 a very high level of competence. Results: the nurses' managers in main Assiut University Hospital are most competent than Pediatric and Women Health Hospital in all competence categories. The level of competence categories in emergency is highest than special & general, intensive care unit and operating room. The total VAS mean levels of competence of all categories ranged from 55.93 to 73.5. Conclusions: nurses' managers have excellent level of competence in work role category, followed by teaching coaching category, then in managing situation category. Main Assiut University Hospital nurses' managers are competent than Pediatric Hospital and Women Health Hospitals in all competence categories. The emergency units nurses' managers are competent than other different work settings following by operating rooms. [Kawther Abd El-Motagally Fadel, Samah Mohamed Abdalah, Fatma Rushdy Mohamed and Eman kamel hossny. competence of Nurses' Managers in Different Work Environment at Assiut University Hospitals . Journal of American Science 2011; 7(6):965-975]. (ISSN: 1545-1003). <http://www.americanscience.org>.

Key words: Competence, nurse manager, work environment.

1. Introduction:

There is no doubt that every member of the society would agree that all healthcare providers in practice should be competent. For nurses to work efficiently and effectively, the areas of competency must be identified for specific roles and settings. Competencies describe the specific job requirements and job environments. Competency-based outcome focus on education and social change abilities, including competent effective reflective practice, generation of nursing knowledge, leadership and social change in order to improved health for individuals, communities, populations, and global environments. Ministries of health, professional organizations, and healthcare organizations must ensure that appropriate expectations for competence are set, and that their staff performs to standard. Healthcare organizations must meet certain criteria to provide services. These

organizations, through certification, licensure, and/or accreditation, are able to exert control on health providers and, as a result, to influence the quality of care (Meretoja, 2004b).

With the increasing complexity of nursing services, hospital employers are demanding qualified and competent staff nurses for high quality clinical practices (Nonaka and Takeuchi, 1995). Employees' perceptions of their performance was proposed as an outcome indicator which would lead to improved quality of provided nursing services and their desire to improve themselves and participate in life-long learning. The imperativeness of studying nurses' self-assessment of their competencies is that, opportunity for learning would contribute to nurses' organizational commitment, which would in turn contribute to improved nursing performance (McNeese-Smith, 2001; Zhang et al., 2001).

Nursing competence usually is defined as personal skills developed through professional nurse training courses, and is considered to be an outcome of these courses. Competence, which is considered an individual characteristic (Archibald and Bainbridge, 1994; DeBack and Mentkowski, 1986), is a group of broad abilities and practical skills that might be changed when the environment changed.

Benner offers a framework of five stages of effective nursing practice that places the competent nurse at the third level. These five stages are: novice, advanced beginner, competent, proficient, and expert (Benner, 1982).

Nowlen (1988) discussed three models of continuing professional development: the update model, the competence model, and the performance model. In competence model, in addition to the knowledge that the professional needs, there are also personal skills (e.g., critical thinking or interpersonal relationships), personal traits (e.g., ethical, takes initiative, self directedness), and a positive self-image required of professional.

Nowadays, competence within the healthcare workforce is an important issue for educators and a concern for employers. Nurses today are required to keep pace with rapid changes in healthcare and provide quality patient care in a cost-efficient manner. Hospitals now compete with an array of outpatient agencies that offer exciting opportunities for the expert, experienced nurse. For this reason, nurse managers must seek ways in which to develop, retain, and reward competent staff (Carey and Campbell, 1994; Jasper, 1994).

Significance of the Study

Researches in nurse competence assessment and studies closely related to this concept have focused upon a relatively narrow area of clinical practice. Most of the work has concentrated on nurse students or on the nurse graduation. There is a lack of researches about assessment of levels of nurses' managers' competence. So, there are some indications that nurse competence profiles must be assessed in different work environment for different levels of nurses' managers.

Aim of the Study

The present study aims to

1. Assess competence of nurses' managers at different work environment at Assuit University Hospitals.
2. Compare nurse's competence at different work environments at Assuit University Hospitals.

2. Subject and Methods

1.1) Study Design

The present study is descriptive.

1.2) Setting

The present study was conducted in all units of Assiut University Hospitals, Main Hospital with bed capacity 1789; Pediatric Hospital with bed capacity 216; Women Health Hospital with bed capacity 303.

1.3) Subjects:-

The present study included all nurses' managers who are working in different departments at the time of the study.

In Main Hospital the total number was seventy five [one director of nursing, three assistant director, fifteen supervisors, and fifty six head nurses]. In Pediatric Hospital the total number was thirty one [one director of nursing, one assistant director, and twenty nine head nurses]. In Women Health Hospital the total number was ten [one director of nursing, one assistant director, one supervisor, and seven head nurses].

1.4) Data collection tool

A personal interview questionnaire sheet which consist of three parts.

1.4.1) Personal characteristics data

It was designed to collect personal data as name, age, department, marital status, educational level, position, years of experience and years of experience of the present position (head nurse, supervisor, assistant director, director of nursing).

1.4.2) Nurse Competence Scale (NCS)

It consists of seventy three items structured in seven competence categories: helping role (seven items), teaching- coaching (sixteen items), diagnostic functions (seven items), managing situations (eight items), therapeutic interventions (ten items), ensuring quality (six items) and work role competences (nineteen items). The competence categories were derived from Benner's model (1984) and Benner et al., (1996) competency frame work.

1.4.3) Scoring System.

The used scoring system is four-point scale (0 = not applicable in my work, 1 = very seldom, 2 = occasionally and 3 = very often in my work). The levels of competence are measured with a Visual Analogue Scale (VAS 0-100 mm), with 0 meaning a very low level of competence, 1-30 mild level of competence, 31-60 good level of competence, 61-99 excellent level of competence and 100 a very high level of competence (Meretoja & Ieino-kilphi, 2003., Meretoja et al., 2004a,b).

2. Administrative Design:

An official permission had been obtained to collect necessary data from administrative responsible personnel of Assuit University Hospitals.

3. Operational Design

3.1) Preparatory phase

This phase took about four months from November 2007 until February 2008. In review the available literatures pertinent to the study topic.

3.2) Pilot Study

A pilot study was fulfilled to test the questionnaire clarity, feasibility, and applicability. It was carried out on thirteen nurses' managers from Assuit University Hospitals. Data collected from the pilot study were analyzed, and necessary modifications were done prior to finalization of the study tool. Clarity has also served in estimating the time needed for filling the forms, and it revealed that each questionnaire would take about 20 minutes for filling. Nurses' manager included in the pilot study was excluded from study sample.

3.3) Data Collection

The researcher met with each subject in the study to explain the purpose of the study and to ask for participation. After obtaining verbal consent, the study tool handles to participated nurse manager to be filled. The data collection was done through structured interview with participants to fill the forms. This took about twenty minutes for each participant interview. The whole duration for data collection took about three months from February to April 2008.

4.) Statistical Analysis

Data entry and analysis were done using SPSS version 12 (Statistical Package for Social Science). Data were presented using descriptive statistics in the form of frequencies and percentages, mean, standard deviation, range and chi-square. For multiple group comparisons of quantitative data, one-way analysis of variance test (ANOVA) was used. Statistical significance was considered at p -value ≤ 0.05 .

3. Results:

Table 1 shows that, half (50.0%) of the studied nurses managers are working in general and special units and 23.3% in the intensive care units. About two thirds of them are less than 30 years old (64.7%), more than half were married (62.1%). The majority of them had bachelor of nursing sciences (94.8%) the minority were having master degree (5.2%), more than three quarters (84.5%) are head nurses. As regard years of experience (44.0 %, 38.7%, and 30.0%) of nurses in main, pediatric and women health hospitals respectively had five to less than ten years of experience. On the other hand more

than half of the studied nurses (58.1%) in Main, Pediatric, and Women Health Hospitals respectively have less than five years experience in nursing administration.

Table 2 reveals that, more than one third of nurses' managers used competencies very often for items of supporting patient's coping strategies, planning patient care according to individual needs, decision making guided by ethical values, Modifying the care plan according to individual need, and developing the treatment culture of their unit(44.9%, 41.4%,40.5%38.8%,37.1%) respectively.

Table 3 reveals that, all items of teaching coaching category were low in percentage, except developing orientation programs for new nurses in her unit, and coaching others in duties within her responsibility area (56.0%, 50.0%).

Table 4 shows that, more than one third of the studied nurses' managers using items of coaching other staff member in patient observation skills, coaching other staff member in use of diagnostic equipment, and developing documentation of patient care(47.4%,44.8%,43% respectively) with a score used very often. While more than one third of the nurses' managers in the study using item of Able to identify family member's need for emotional support (35.4%) with a score used of very seldom.

Table 5 illustrates that, 59.5%, 60.3% of studied nurses' managers used very often items of acting appropriately in life threatening situations, and keeping nursing care equipment in good condition respectively. While the lowest percentage of them using item of promoting flexible team cooperation in rapidly changing situations (5.2%) either not applicable or very seldom for both.

Table 6 depicts that, more than one third of studied nurses' managers used very often for all items of therapeutic interventions except items of utilizing research finding in nursing interventions, and evaluating systematically patient care outcomes (16.4%, 26.7%). Also, one third of the nurses' managers in the study used occasionally all items of therapeutic interventions. While the low percentage of nurse's manager not applicable for items of coordinating multidisciplinary team's nursing activities (3.4%).

Table 7 reveals that, more than one third of studied nurses' managers used occasionally for all items except items of able to identify areas in patient care needing further development and research, and evaluating critically unit's care philosophy half of them used occasionally(50,8%,51.7%).

Table 8 shows that, the highest percent of studied nurses' used very often for items of mentoring novices and advanced beginner, aware

of the limits of their own resources, and familiar with their organization's policy concerning division of labor and coordination of duties (63.8%,58.6%,56.9%) respectively. While the low percent for both items of taking care of themselves in terms of not depleting their mental and physical resources, and utilizing information technology in their work (20.7%).

Table 9 shows that mean scores of competence categories of the nurses' managers. The nurses' managers in main Assuit University Hospital are most competent than other two hospitals in all competence categories (13.74±4.40; 29.72±10.18; 13.73±4.81; 17.85±5.04; 21.21±5.73; 10.53±4.28; 43.42±8.77). And there were statistically significant differences among Assuit University Hospitals as regarded to work role category at p value ($P \leq 0.018$).

Table 10 provides data on the studied nurses' managers' level of competence. The level of competence categories in emergency is highest than all other work environment (66.96, 65.75, 72.32, 78.38, 74.99, 65.27, 80.15). The total VAS mean levels of competence of all categories ranged from 55.93 to 73.50.

Table 11 reveals that, the studied nurses' manager of main Assuit University Hospital have excellent level of competence than other two hospitals in all competence categories, helping role; teaching coaching; diagnostic functions; managing situations therapeutic interventions; ensuring quality; and work role (69.3%, 56.%, 68.%, 80.%, 76.%, 57.3% and 89.3%), and there were statistically significant differences among three university hospitals as regarded to categories of managing situations and work role at p value ($P \leq 0.033; 0.020$).

Table (1): Personal characteristics of the nurses' managers at Assuit University Hospitals (n=116)

Table (4): Distribution of diagnostic functions category among the studied nurses' managers at Assuit University Hospitals (n=116)

Items of Diagnostic Functions category	Not applicable		Used very seldom		Used occasionally		Used very often	
	No.	%	No.	%	No.	%	No.	%
1- Analyzing patient well-being from many perspective	12	10.3	24	20.7	42	36.2	38	32.8
2- Able to identify patient's need for emotional support	17	14.6	29	25.0	40	34.5	30	25.9
3- Able to identify family member's need for emotional support	26	22.4	41	35.4	37	31.9	12	10.3
4- Arranging expert help for patient when needed	7	6.1	20	17.2	45	38.8	44	37.9
5- Coaching other staff member in patient observation skills	4	3.4	21	18.1	36	31.1	55	47.4
6- Coaching other staff member in use of diagnostic equipment	7	6.1	24	20.7	33	28.4	52	44.8
7-Developing documentation of patient care	9	7.8	17	14.7	40	34.5	50	43.0

Table (5): Distribution of managing situations category among the studied nurses' managers at Assuit University Hospitals (n=116)

Managing Situations category	Not applicable		Used very seldom		Used occasionally		Used very often	
	No.	%	No.	%	No.	%	No.	%
1- Able to recognize situations posing a threat to life early	6	5.2	22	19.0	34	29.3	54	46.5
2- Prioritizing her activities flexibly according to changing situations	9	7.8	20	17.2	41	35.3	26	39.7
3- Acting appropriately in life threatening situations	4	3.4	14	12.1	29	25.0	69	59.5
4- Arranging debriefing session for the care team when needed	13	11.2	15	12.9	48	41.4	40	34.5
5- Coaching other team member in mastering rapidly changing situations	9	7.8	19	16.5	50	43.1	38	32.7
6- Planning care consistently with recourses available	5	4.3	19	16.2	43	37.3	49	42.2
7- Keeping nursing care equipment in good condition	6	5.1	7	6.2	33	28.4	70	60.3
8- Promoting flexible team cooperation in rapidly changing situations	6	5.2	6	5.2	51	44.0	53	45.6

Table (6): Distribution of therapeutic interventions category among the studied nurses' managers at Assuit University Hospitals (n=116)

Therapeutic Interventions	Not applicable		Used very seldom		Used occasionally		Used very often	
	No.	%	No.	%	No.	%	No.	%
1- Planning own activities flexibly according to clinical situation	14	12.1	8	6.9	55	47.4	39	33.6
2- Making decisions concerning patient care taking the particular situation in account	14	12.1	16	13.8	42	36.2	44	37.9
3- Coordinating multidisciplinary team's nursing activities	4	3.4	15	12.9	46	39.7	51	44.0
4- Coaching the care team in performance of nursing intervention	7	6.0	14	12.1	50	43.1	45	38.8
5- Updating written guidelines for care	14	12.0	15	12.9	46	39.7	41	35.4
6- Providing consultation for the care team	7	6.1	12	10.3	40	34.5	57	49.1
7- Utilizing research finding in nursing interventions	25	21.6	23	19.8	49	42.2	19	16.4
8-Evaluating systematically patient care outcomes	9	7.8	28	24.1	48	41.4	31	26.7
9- Incorporating relevant knowledge to provide optimal care	10	8.6	14	12.1	42	36.2	50	43.1
10- Contributing to further development of multidisciplinary clinical paths	10	8.6	21	18.1	38	32.8	47	40.5

Table (7): distribution of ensuring quality category among the studied nurses' managers at Assuit University Hospitals (n=116)

Ensuring Quality category	Not applicable		Used very seldom		Used occasionally		Used very often	
	No.	%	No.	%	No.	%	No.	%
1- Committed to her organization's care philosophy	19	16.4	19	16.4	42	36.2	36	31.0
2- Able to identify areas in patient care needing further development and research	14	12.1	21	18.1	59	50.8	22	19.0
3- Evaluating critically unit's care philosophy	20	17.2	22	19.0	60	51.7	14	12.1
4-Evaluating systematically patient's satisfaction with care	10	8.6	23	19.8	51	44.0	32	27.6
5- Utilizing research findings in further development of patient care	22	19.0	29	25.0	44	37.9	21	18.1
6- Making proposals concerning further development and research	21	18.1	34	29.3	50	43.1	11	9.5

Table (8): Distribution of work role category among the studied nurses' managers at Assuit University Hospitals (n=116)

Work Role category	Not applicable		Used very seldom		Used occasionally		Used very often	
	No.	%	No.	%	No.	%	No.	%
1- Able to recognize college's need for support and help	3	2.6	9	7.8	44	37.9	60	51.7
2- Aware of the limits of my own resources	3	2.6	13	11.2	32	27.6	68	58.6
3- Professional identity service as resource in nursing	4	3.4	16	13.8	55	47.4	41	35.4
4- Acting responsibly in term of limited financial resources	4	3.4	13	11.2	49	42.2	50	43.2
5- Familiar with organization's policy concerning division of labor and coordination of duties	3	2.6	13	11.2	34	29.3	66	56.9
6- Coordinating student nurse mentoring in the unit	7	6.0	19	16.4	42	36.2	48	41.4
7- Mentoring novices and advanced beginner	3	2.6	10	8.6	29	25.0	74	63.8
8- Providing expertise for the care team	6	5.2	12	10.3	49	42.2	49	42.3

*(P≤0.05)

4. Discussion

The nurse manager is accountable for excellence in the clinical practice of nursing and the delivery of patient care on a selected unit within the health institution. This function is the primary focus of the nurse manager to meet this responsibility. The nurse manager has the authority to plan and implement strategies and programs consistent with the organization policies, goals, and objectives, as well as with professional standard. The manager is responsible for safe and caring environment that promote health teaching. The manager is responsible for assessing patient and family response to nursing care as well as evaluating the effectiveness and quality of care and services (Sullivan & Decker, 2005).

The present study confirms that regarding departments exactly half of study subjects who work in general and special units in different hospitals in the study while less than one quarter of them working in the intensive care units in the same hospitals. Regarding age, about two thirds of nurses' managers were less than thirty years old; more than one third of them have experience from five to less than ten years. Accordingly they have short years of experience (table, 1). These results is might be attributed to nurses' managers were from Pediatric and Women Health Hospital and these hospitals are new. This means that they will be in the work force for long years. To perform competently, personal characteristics are contributing factors to their development that have to be continuously identified and fulfilled.

More than half of nurses' managers are married; the majority of them had bachelor sciences of nursing, and more than three quarters of them head nurses. Defloor et al., (2006) clarify that the continuous presence of nurses' managers with experience and additional education will be necessary, particularly in emergency situations and they should be available for consultation

These results are in accordance with (McCloskey and McCain, 1988) who mentioned that the degree of education nurses had received best distinguished top and medium performers from poor performers during the first year of work. The level of experience was the best predictor of critical care skills. The top performers had also more feedback from supervisors than the poor performers. The results of their study also indicated that education, job satisfaction and feedback are determinants of job performance. In addition, they view the importance of manager leadership skills, manager expectations and communications with nurses are important for effective performance.

In the present study from competence categories (individual competencies), the nurses'

managers considered most competent in developing orientation program for new nurses in their units, coaching other staff member in patient observation skills. These may be attributed to implementation of an orientation program to all new graduated is an old rule for head nurses and staff nurses in Assuit University Hospital. The role of nurses' managers to coach staff nurses as a job description for them and nurses' managers considered least competent in developing patient education in their units. Moreover, decisions taken in particular situation and in providing ethical and individualized care (tables, 2, 3). This result is consistent with Bartlett et al., and Scholes et al., (2000) who mentioned that the importance of combining ethics and values, reflective practice, context-specific knowledge and skills are elements of competent performance.

Also, nurses' managers are considered most competent in keeping nursing care equipment in good condition. This indicates the presence of internal commitment and feeling of responsibility toward their units accordingly to their organization and least competence in coaching team members in mastering rapidly changing situations (tables, 5).

Least competent nurses were in evaluating patient education outcomes, utilizing research findings and contributing to further development of patient care (tables, 2, 6, 7, 8). This may be attributed to lack of integration and collaboration between nursing service and nursing education in the form of no research findings and recommendations applied in the hospital and also nurses' managers did not try to know what are new researches results are and they never read after graduate. Low competence in research utilization is verified by O'Conner et al., (2000) who clarify that nurses in general medical and surgical wards not utilize research finding in clinical practice while differ from the findings of McCaughan and Parahoo, (2001) who mentioned that, more than half percent of medical and surgical nurses utilize research in clinical practice.

In Assuit University Hospitals nurse's managers considered that they were most competent as regard to work role category and there are a statistically significant differences between three hospitals regarding this category, followed by teaching-coaching category in the same Hospitals (table, 9). This may be attributed to that, Assuit University Hospitals considered a teaching based hospitals and the hospital have a training center, and every nursing staff members had a clear work role in order to be a role model in the work environment. As emphasized by (Meretoja and Leino-Kilpi, 2003) in their study of competence assessment made by nurse managers and practicing nurses, in which nurses'

managers assessed nurses more competent in teaching coaching category.

Assessment levels of competence as regard to competence categories in different work environments. The finding of the present study revealed that, the nurses' managers level of competences considered as excellent. The total VAS mean levels of competence of all categories ranged from 56 to 73. The nurses' managers considered that they were most competent in skills and tasks falling into the categories of managing situations, helping role and diagnostic functions (table, 10). This result is consistent with Meretoja, (2002) who clarifies that, the university hospital setting were high patient acuity and short length of stay that reflect great complexity, high risk patients and the need of rapid nursing responses to patient care.

The findings of the present study show that, nurses' managers related their own competence as excellent in three Assuit University Hospitals and there were statistically significant differences among the three hospitals as regarding to work role and managing situation categories (table, 11). It might be attributed to that, the main Assuit University Hospital is the oldest hospital and nurse managers are more experienced and received more training programs in clinical service than those of pediatric and women hospitals, in which they are new developed and less experienced employees. This result is inconsistent with Harisson and Nixon (2002) who mentioned that, the organizational culture, and the environment of care or resources available may have an effect on how nurses define the purpose of nursing and prioritize nursing actions.

Conclusions

In the light of the study results, the following conclusions can be drawn:

- 1- Nurses' managers have excellent level of competence in work role category, followed by teaching coaching category, then in managing situation category.
- 2- Main Assuit University Hospital nurses' managers are competent than Pediatric Hospital and Women Health Hospitals in all competence categories.
- 3- The emergency units nurses' managers are competent than other different work settings following by operating rooms.

Recommendations

Based on the forgoing conclusions, the following recommendations are proposed:-

- 1- Developing a career ladder for different nursing categories to encourage nurses' managers to improve their level of competency.

- 2- Developing a Performance appraisal tool specific for nursing categories to recognize and promote them based on career ladder.
- 3- Continuing education (in the form of workshops or training courses) to nurses' managers regarding developing patient education and how to deal with rapidly changing situations.
- 4- More researches are needed to evaluate the outcomes of competencies not only in terms of individual nurses but also in terms of patient and unit outcomes.

Online Classes and Traditional Classes in adult education

Mina Abarashi

Damavand Branch, Islamic Azad University, Damavand, Iran
Email: sharif11070@yahoo.com

Abstract: Distance education places students and their instructors in separate locations using some form of technology to communicate and interact. The student may be located in the classroom, home, office or learning center. The instructor may be located in a media classroom, studio, office or home. Distance education delivers classes (live or pre-taped) to students in their home, office, or classroom. It is used by K-12, higher education, continuing education and business. As the cost of delivering quality education increases, institutions find that limited resources prevent them from building facilities, hiring faculty, or expanding curricula. They are using distance education to maximize resources and are combining their assets with others to produce programming. Distance education is offered internationally, nationally, regionally, and locally over all forms of conferencing technology. The student may receive information via satellite, microwave, or fiber optic cable, television (broadcast, cable or Instructional Television Fixed Services (ITFS)), video cassette or disk, telephone - audio conferencing bridge or direct phone line, audio cassette, printed materials - text, study guide, or handout, computer - modem or floppy disk, and compressed video. Recent rapid development of technology has resulted in systems that are powerful, flexible, and increasingly affordable. The base of available information technology resources is increasing with dramatic speed. Much has been learned about connecting various forms of technology into systems, so that the ability to link systems is growing. Most distance learning systems are hybrids, combining several technologies, such as satellite, ITFS, microwave, cable, fiber optic, and computer connections.

Keywords: Online Classes, Traditional Classes, distance education

Introduction:

Led the way when dealing with those massive training programs available to speak to the technological tools that we expect to occur that planners and decision makers that planners and decision makers of large structures, especially university education according to the image Access to the development of community information are available on these tools are selected and used. Massive wave of data produced in today's world it nicknamed the "information age" has all day and through various means of communication in the world will move on its size are added. Other hand, as we're not the world witnessed the development of the role of information communication devices transporting feedback fast and absorb the information around the world, we forget.

Therefore, information and communication as the main lever or two important move in developing wings, we learn. Meanwhile, proper utilization of the capacities of these two valuable and effective indexes in the general development concept for any society and the principles of a critical need is considered. With a view to clarifying this issue can be paid in the best way to create a platform for developing data standards and access to a knowledge based society, what really can be. To achieve a clear and practical

answer in this area before all the existing definitions and indicators mentioned placed.

Distance education is a method of education in which the learner is physically separated from the teacher and the institution sponsoring the instruction. It may be used on its own, or in conjunction with other forms of education, including face-to-face instruction. In any distance education process there must be a teacher, one or more students, and a course or curriculum that the teacher is capable of teaching and the student is trying to learn. The contract between teacher and learner, whether in a traditional classroom or distance education, requires that the student be taught, assessed, given guidance and, where appropriate, prepared for examinations that may or may not be conducted by the institution. This must be accomplished by two-way communication. Learning may be undertaken either individually or in groups; in either case, it is accomplished in the physical absence of the teacher in distance education. Where distance teaching materials are provided to learners, they are structured in ways that facilitate learning at a distance.

What do the education institutions offer?

Archived video footage and virtual real-time lectures, online assignments and presentations, electronic academic material, multimedia as part of

classrooms – all these have been part of higher education for a while now.

However, Online Education means taking entire degree program online, via your laptop. This means an entirely new experience, yet not everybody is ready for it.

Taking Online Classes via Online education program requires specific learning skills, which some people lack.

The Pros of Online Classes

The key advantages of using an online class are –

1. Time flexibility

For some people there is nothing worse than getting up before 9 in the morning. Traditional higher education often requires just that. But with online education students have the possibility to adjust schedules to their life, rather than adjust their life to predetermined schedules. Other people benefit greatly from it too: parents, full-time employees, and anyone else who for this or that reason is too busy to attend traditional classes.

2. Geographic flexibility

Online institutions make possible something unprecedented: it no longer matters where you live. You can live in one of the world and study daily at an institution based in another without ever leaving your native country, or even your room, for that matter. Even in terms of local travel online education is a revolution: there are no more bus, train, or car trips, no traffic jams, no being late for the bus/train, no time and money spent on travel.

3. Class Notes

Not everybody knows how to write great class notes. Online courses provide electronic transcripts of every lecture. This is great for anyone who has short attention spans or does not like to write during lectures.

4. More educational means

Much more so that in traditional classrooms, online education incorporates online multimedia possibilities into instruction.

Possible cons of online classes include:

What are the Disadvantages of Online Courses? Here are some –

1. Credits:

Not all online course credits are transferable to traditional degree programs!

2. Require self-discipline

Excellent self-discipline and time management without the aid of strict schedules, attendance requirements, and personal communication

3. Lack of interpersonal interaction

No interpersonal relationships with other teachers or students; only via email, message boards, and other online means of communication.

Disadvantages of Online Classes: Disadvantages to Consider

This article will focus on the disadvantage of taking Online Classes. Online education is not exactly a trend yet, but it is becoming increasingly popular.

The reason for this is that it offers new opportunities where none existed before – Many people wouldn't have been able to acquire the necessary higher education without it. However, like all things in life, taking Online Classes has some drawbacks and disadvantages as compared to the traditional classrooms.

That said, online classes are not perfect for everyone. To avoid getting caught in the hype and making the wrong decision, consider the pros and cons of online education.

Online Classes VS Traditional Classes: Comparison between the Two Methods

Nowadays it is not enough to choose the university you want to learn at. Today, you have to first decide whether you want an online degree or an offline/traditional education.

Online education is a growing force in the field of additional and higher education. It is probable that in the near future, within a decade or two, online education will be the global standard.

Considering the differences between these two methodologies of education can provide you the basic knowledge and even surprising opportunities.

Online VS Traditional Classes

Attendance

Traditional institutions require physical presence and participation in classrooms. This entails extensive travel and expenses. For many only this already makes higher education impossible. Online education requires no traveling at all, saving time, money, and energy. Busy people will therefore be able to combine extensive studies with work and family. Education is available to sailors on submarines and to astronauts in space!

Virtual classrooms vs. real classrooms

There are two camps around this issue – Those who love attending campus-based lecture and those would rather stay at home. Virtual education means there are no campuses and no classrooms. For those who prefer to be at home and are comfortable with cyberspace this is a virtual paradise. For those who are technophobic, get confused by online multi-media, and who prefer direct human contact this may be a veritable digitalized hell. But the amount of people who are uncomfortable with technology and the

internet is decreasing exponentially. Most people are addicted to the internet. And video communication is becoming standard nowadays, allowing top-quality group video communication online.

Traditional and Online Schedules

Online institutions deliver many or all courses via modules.

These modules can be scheduled by the student him or herself to be taken virtually at any time of day or night. This is obviously impossible with traditional classes, however requires a high degree of self-motivation and the ability to meet requirements while enjoying greater freedom.

The Value of online classes/degree earned as compared to the traditional ones

When it comes to quality, going to Online Classes becomes universal as going to a traditional college class.

One has to remember that the world is changed rapidly and the online education is now a great alternative to the traditional one. Just like a person got used to choose between campus-based colleges and universities, today the online education grows to be an option. Of course, with its different varying quality of degrees, just like any on-campus degrees.

Conclusion:

Distance education delivers classes (live or pre-taped) to students in their home, office, or classroom. It is used by K-12, higher education, continuing education and business. As the cost of delivering quality education increases, institutions find that limited resources prevent them from building facilities, hiring faculty, or expanding curricula. They are using distance education to maximize resources and are combining their assets with others to produce programming. Distance education is offered internationally, nationally, regionally, and locally over all forms of conferencing technology.

The student may receive information via satellite, microwave, or fiber optic cable, television (broadcast, cable or Instructional Television Fixed Services (ITFS), video cassette or disk, telephone - audio conferencing bridge or direct phone line, audio cassette, printed materials - text, study guide, or handout, computer - modem or floppy disk, and compressed video. Recent rapid development of technology has resulted in systems that are powerful, flexible, and increasingly affordable. The base of available information technology resources is increasing with dramatic speed. Much has been learned about connecting various forms of technology into systems, so that the ability to link systems is growing. Most distance learning systems are hybrids, combining several technologies, such as

satellite, ITFS, microwave, cable, fiber optic, and computer connections.

Interactivity is accomplished via telephone (one-way video and two-way audio), two-way video or graphics interactivity, two-way computer hookups, two-way audio. Interactivity may be delayed but interaction provided by teacher telephone office hours when students can call or through time with on-site facilitators. Classes with large numbers of students have a limited amount of interactivity. Much of the activity on computer networks is on a delayed basis as well. Possibilities for audio and visual interaction are increasingly wide.

Challenges which faced the early users of distance education are still with us today. If distance education is to play a greater role in improving the quality of education, it will require expanded technology; more linkages between schools, higher education, and the private sector; and more teachers who use technology well. Teachers must be involved in planning the systems, trained to use the tools they provide, and given the flexibility to revise their teaching. Federal and state regulations will need revision to ensure a more flexible and effective use of technology. Connections have been established across geographic, instructional, and institutional boundaries which provide opportunities for collaboration and resource sharing among many groups. In the pooling of students and teachers, distance learning reconfigures the classroom which no longer is bounded by the physical space of the school, district, state or nation.

Abstract: Challenges which faced the early users of distance education are still with us today. If distance education is to play a greater role in improving the quality of education, it will require expanded technology; more linkages between schools, higher education, and the private sector; and more teachers who use technology well. Teachers must be involved in planning the systems, trained to use the tools they provide, and given the flexibility to revise their teaching. Federal and state regulations will need revision to ensure a more flexible and effective use of technology. Connections have been established across geographic, instructional, and institutional boundaries which provide opportunities for collaboration and resource sharing among many groups. In the pooling of students and teachers, distance learning reconfigures the classroom which no longer is bounded by the physical space of the school, district, state or nation. Distance education can be used for some aspects of most disciplines. For example, several institutions of higher education already have developed certificate programs, undergraduate programs, and graduate programs in health and physical education that are delivered using distance education methods.

[Fatemeh Vahidi. **Distance Education and e-learning: Similarities and differences.** Journal of American Science 2011;7(6):980-984]. (ISSN: 1545-1003). <http://www.americanscience.org>.

Keywords: Distance Education, E-learning

Introduction:

Distance education is education designed for learners who live at a distance from the teaching institution or education provider. It is the enrollment and study with an educational institution that provides organized, formal learning opportunities for students. Presented in a sequential and logical order, the instruction is offered wholly or primarily by distance study, through virtually any media. Historically, its predominant medium of instruction has been printed materials, although non-print media is becoming more and more popular. It may also incorporate or make use of videotapes, CD or DVD ROM's, audio recordings, facsimiles, telephone communications, and the Internet through e-mail and Web-based delivery systems. When each lesson or segment is completed, the student makes available to the school the assigned work for correction, grading, comment, and subject matter guidance by qualified instructors. Corrected assignments are returned to the student. This exchange fosters a personalized student-instructor relationship, which is the hallmark of distance education instruction. Historically, most distance education courses were vocational in nature, but today courses are offered for academic, professional, and avocational purposes for students of all ages. There are numerous specialized programs, such as those for blind persons and for parents of small children with hearing impairments. Distance education is available in practically any

field, from accounting to zoology. Courses are offered in gemology, high school diploma, journalism, locksmithing, child day care management, yacht design, and many fascinating subjects. Distance education courses also vary greatly in scope, level, and length. Some have a few assignments and require only a few months to complete, while others have a hundred or more lesson assignments requiring three or four years of conscientious study. Since 1890, more than 130 million Americans have studied at DETC member institutions, including Franklin D. Roosevelt, Walter P. Chrysler, Walter Cronkite, Barry Goldwater, Charles Schulz, and many other distinguished alumni of DETC members. Unlike most distance education courses offered by traditional colleges and universities that are semester and classroom oriented, with courses offered by most of the DETC-accredited institutions you can study any time and anywhere. Distance education is especially suited for busy people who wish to increase their knowledge and skills without giving up their jobs, leaving home, or losing income. You learn while you earn. Many courses provide complete vocational training; others prepare you for upgrading in your present job, without losing wages, experience or seniority. You receive individual attention, and you work at your own pace. In recent years, technology has played a significant role in transforming the traditional distance education school into a dynamic, interactive distance learning method using toll-free telephone lines, as well as a diverse array of personal computers, video devices, CD and DVD ROMs,

online courses over the Internet, interactive devices, and other modern technological innovations. The future for distance study promises to be exciting.

Educational methods in distance learning:

Today, under the new system replaced the traditional systems of learning and learning week (ie tutoring methods, lectures) are:

- Multimedia courses:

These courses and widely used elements of image, communication, graphics and simulated components, animation and communication elements for guidance and tips, and talk back on course and curriculum issues are held.

- Enhanced communication mechanisms:

The mechanism of any texts simultaneously, and asynchronous audio-visual communications to protect you. This case allows students to practice on topics learned will give.

- Written test:

thus, question and test via a distributed communication network, are corrected and returned. These exams through video conferencing support and runs.

- Virtual Seminar:

thereby different groups of students in different geographical environments linked together makes.

- Collaborative virtual laboratories:

the laboratory of the Group's activities are supported. Workshops such as software engineering.

-Smart academic factors:

academic factors that inform intelligent, support and guidance students pay.

Key factors in the process of distance education:

the process of remote training, the following factors contribute:

- Students:

Regardless of educational content, role and main element in the learning process students are responsible.

- Coaches and Teachers:

Success depends on a lot of educational activities the ability, skills and knowledge are the coaches and professors.

- Facilitators of communication:

Facilitator bases, as the bridge between students and mentors are. Must base expectations of teachers and educational needs of students and service coordination and communication to create.

- Support staff:

One of the important pillars of any development of distance education programs, by development group finds. Operational support staff such as student registration, copy and distribute their resources,

order textbooks, security and copyright, and are responsible for the report.

- Management:

The group decision makers, builders and judges are considered to be educational and should be considered among the factors above, establish the correct relationship formation.

In its original form, teachers using distance education traveled to remote sites and taught a class, or corresponded with students through mail, telephone, or fax machine. Individualized study has been a method of reaching the remote student for some time. Detailed course instructions are sent to the learner who performs the assigned tasks and returns the completed work to the teacher for evaluation and reassignment if necessary.

Technology has raised the quality of individualized distance instruction. The use of various forms of electronic media increases time effectiveness and improves the delivery of information. Video, audio, and computer-based applications may enhance the product received by the independent learner. Electronic delivery can occur using synchronous communication, in which class members participate at the same time, or asynchronous communication where participants are separated by time (Romiszowski, 1993).

Video/audio models of distance education include broadcast television, cable television, satellite, microwave, fiber optics, and audio graphics. The most widely used format is broadcast and cable television (Parrott, 1995). However, developments in satellite and fiber optic systems have produced other successful programs. The interactive capability of many of these networks has produced a distance classroom that is nearly identical to a regular classroom. Teachers and students can interact through both two-way video and one-way video with two-way audio systems. The recent development of Desktop Video Conferencing (DVC) which brings interactive video capability to the desktop computer, further enhances learning opportunities.

The linking of computer technology through the use of the Internet or CD-ROM with television transmission provides a potentially new dimension to distance education. This technique can link university professors to high school teachers, or to physically disabled students, in a distance setting (McLean, 1996).

Another form of interaction is the use of computer conferencing. This method utilizes asynchronous communication in such forms as an e-mail list group, an Internet discussion group, or other types of conferencing software. Asynchronous methods of communication are especially appealing to the

learner who has difficulty scheduling specific time- and place-bound course work.

The main aspects of Distance Education are as follows-

1. Geography: The point of Distance Education is to educate despite geographical differences. Online education effectively abolishes geographical as well as time differences, allowing an unprecedented number of students from all over the world to study in an institution, at any time of day.

2. Why higher education and Why take it from Distance: The world of today requires advanced education. Nowadays, advanced degrees are the standard – Having more than one education is not extraordinary but sometimes a must. Foreign studies are also common.

With the increased penetration of the Internet, Distance Education, offering anything from individual classes to complete doctoral degrees online, is a natural development of modern educational processes and requirements.

3. Distance Education as we know it today: It is a web-based education developed using e-Learning software tools and other distance-communication means. With increasing reliance on information, the demand for better and faster education grew and brought about the Internet.

4. Who Uses Distance Education? More and more people acquire higher education. Even professionals with full-time careers acquire new degrees, without change of pace at work. Distance education is perfect for the Military and for social institutions of all kinds. Parents can now combine higher education with family. Foreign education has never been easier – all it takes now is to log on.

Distance Education reaches out to all those segments of population which only a decade or so ago were almost completely neglected by educational systems.

In the nearest future cultural, educational, corporate diversity will reach never-before-seen peaks.

Distance education is any type of schooling that takes place away from a physical campus. Distance education is also known as:

- distance learning
- virtual learning
- online learning
- e-learning
- online education
- web-based training

Conclusion:

Distance education places students and their instructors in separate locations using some form of technology to communicate and interact. The student may be located in the classroom, home, office or

learning center. The instructor may be located in a media classroom, studio, office or home.

Technology transports information, not people. Distances between teachers and students are bridged with an array of familiar technology as well as new information age equipment. What sets today's distance education efforts apart from previous efforts is the possibility of an interactive capacity that provides learner and teacher with needed feedback, including the opportunity to dialogue, clarify, or assess. Advances in digital compression technology may greatly expand the number of channels that can be sent over any transmission medium, doubling or even tripling channel capacity. Technologies for learning at a distance are also enlarging our definition of how students learn, where they learn, and who teaches them. No one technology is best for all situations and applications. Different technologies have different capabilities and limitations, and effective implementation will depend on matching technological capabilities to education needs.

The student may receive information via satellite, microwave, or fiber optic cable, television (broadcast, cable or Instructional Television Fixed Services (ITFS), video cassette or disk, telephone - audio conferencing bridge or direct phone line, audio cassette, printed materials - text, study guide, or handout, computer - modem or floppy disk, and compressed video. Recent rapid development of technology has resulted in systems that are powerful, flexible, and increasingly affordable. The base of available information technology resources is increasing with dramatic speed. Much has been learned about connecting various forms of technology into systems, so that the ability to link systems is growing. Most distance learning systems are hybrids, combining several technologies, such as satellite, ITFS, microwave, cable, fiber optic, and computer connections.

Interactivity is accomplished via telephone (one-way video and two-way audio), two-way video or graphics interactivity, two-way computer hookups, two-way audio. Interactivity may be delayed but interaction provided by teacher telephone office hours when students can call or through time with on-site facilitators. Classes with large numbers of students have a limited amount of interactivity. Much of the activity on computer networks is on a delayed basis as well. Possibilities for audio and visual interaction are increasingly wide.

In the earlier days of distance learning, it was most common to see distance learning used for rural students who were at a distance from an educational institution. The student might watch a telecourse on a television stations, read texts, mail in assignments and then travel to the local college to take an exam.

This model is still in use, but as the technology has become more sophisticated and the cost of distance learning dropped as equipment prices dropped, the use of distance education has increased.

High front-end costs prevented an early widespread adoption of electronically mediated learning. Distance learning has been aggressively adopted in many areas because it can meet specific educational needs. As the concept of accountability became accepted and laws required certain courses in high school in order for students to be admitted to state colleges, telecommunications was examined as a way to provide student access to the required courses. Many rural school districts could not afford the special teachers to conduct required courses. Distance education met this need by providing courses in schools where teachers were not available or were too costly to provide for a few students. It also fulfilled a need for teacher training and staff development in locations where experts and resources were difficult to obtain. These systems link learner communities with each other and bring a wide array of experts and information to the classroom.

Challenges which faced the early users of distance education are still with us today. If distance education is to play a greater role in improving the quality of education, it will require expanded technology; more linkages between schools, higher education, and the private sector; and more teachers who use technology well. Teachers must be involved in planning the systems, trained to use the tools they provide, and given the flexibility to revise their teaching. Federal and state regulations will need revision to ensure a more flexible and effective use of technology. Connections have been established across geographic, instructional, and institutional boundaries which provide opportunities for collaboration and resource sharing among many groups. In the pooling of students and teachers, distance learning reconfigures the classroom which no longer is bounded by the physical space of the school, district, state or nation.

²Pediatric Medicine Dept., Faculty of Medicine, University of Alexandria, Egypt
nehadbasiouny@yahoo.com

Abstract: Leukemia is the most common childhood cancer. Untreated leukemia results in death from infections or hemorrhage. The primary treatment of ALL is chemotherapy which is usually associated with a number of side effects among which is oral mucositis (stomatitis). It is one of the most debilitating complications following chemotherapy treatment administration. These lesions may produce discomfort and pain which interfere with eating, patient compliance to treatment and potential risk of oral infection. Good and consistent oral hygiene is one of the basic roles of the pediatric nurse to prevent and reduce the complication of oral infection. It includes oral assessment before the initiation of chemotherapy treatment and during its administration followed by creating an oral care plan. Chlorhexidine gluconate is effective in the prevention of oral lesion and in decreasing the severity of stomatitis. The aim of the present study is to determine the effect of using chlorhexidine gluconate in the prevention of oral lesions in leukemic children receiving chemotherapy. The study was conducted at the Haematology Unit of Alexandria University Children's Hospital at EL-Shatby and at the Oncology department at the Health Insurance Student Hospital in Alexandria. The subjects of this study comprised 50 children of both sexes with acute lymphoblastic leukemia. Children were divided into two groups: group I (study group) received 0.1 % of chlorhexidine gluconate and group II (control group) who was left to the routine hospital care. Tool consisted of three parts to collect the study data: Children's Bio socio-demographic data; Children's Medical data; Oral assessment guide (OAG) tool. The main result showed that children among the study group had healthier oral cavity and lower degree of oral mucositis no one developed severe oral mucositis compared to the children in the control group following 10 days of chemotherapy administration. The main recommendation is to create an oral care plan to each child individually involving cleaning teeth by using a mouth wash with Chlorhexidine gluconate. This is important for preventing oral complications, decreasing severity of oral mucositis and treating gingivitis (swelling, redness and bleeding of the gums).

[Azza M. Darwish; Mostafa A. S. Salama; Nehad S. Basiouny and Noha M. Arafa. Effect of Chlorhexidine in Prevention of Oral Lesions in Leukemic Children Receiving Chemotherapy. Journal of American Science 2011; 7(6):985-996].(ISSN: 1545-1003). <http://www.americanscience.org>.

Key words: lymphoblastic leukemia, chemotherapy, oral mucositis, Chlorhexidine gluconate.

1. Introduction:

Malignant diseases are one of the most common causes of death among children below the age of 15 years after accidents⁽¹⁾. Among childhood malignancies, leukemia, is the most common childhood cancer accounting for about one third of pediatric malignancies^(2,3).

Chemotherapy is usually associated with a number of side effects mainly nausea, vomiting, anorexia, alopecia, neuropathy, constipation, hemorrhagic cystitis, moon face, mood changes and oral mucositis^(4,5). Oral mucositis (stomatitis) is one of the most debilitating complication following chemotherapy administration. Stomatitis is an inflammation of the oral mucosa which may include the cheek, lips, tongue, palate and floor of the mouth^(6,7). Oral mucositis can occur in any region of the mouth but more frequently affects non-keratinized regions such as the buccal mucosa, soft palate and the floor of the mouth⁽⁸⁾.

Oral mucositis normally lasts for 3 weeks. It begins on the 3rd-5th day from starting chemotherapy with a peak on the 7th-14th day after chemotherapy.^(9,10) Mucositis is caused by direct effect of chemotherapy by interfering with actual cell production, maturation and replacement and indirectly due to bone marrow depression during which neutropenia and thrombocytopenia lead to increased risk of bleeding and infection^(11,12). The severity of oral mucositis depends on the type of chemotherapeutic drug, dosage, frequency of drug administration, the child's age, neutrophil count and level of oral care^(11,12).

Preventive care for oral mucositis is very important especially in patients receiving high-doses of chemotherapy. Consistent oral hygiene is one of the basic roles of the pediatric nurse in the prevention and reduction of the severity of oral mucositis and oral infection. It includes oral assessment before the initiation of chemotherapy and daily assessment

during chemotherapy administration then creating an oral care plan⁽¹³⁾.

There are different substances used in mouth care such as hydrogen peroxide, saline rinse, and herbal medicine as chamomile⁽¹⁴⁾. Other preparations that are used to prevent or treat mucositis include 12% Chlorhexidine gluconate because of its dual action against candidal and bacterial infection^(15,6).

Chlorhexidine gluconate is a biguanide antiseptic and disinfectant. It is effective against both gram-positive and gram-negative bacteria but more effective against Gram-positive bacteria. It has been shown to have an immediate bactericidal action and a prolonged bacteriostatic action. It inhibits some virus and it is also active against some fungi. It acts by disrupting the bacterial cells plasma membrane. Chlorhexidine gluconate is used to treat gingivitis (swelling, redness, and bleeding of the gums).^(16,17) It is often used as an active ingredient in mouthwash designed to kill dental plaque and other oral bacteria so it is used to improve bad breath.⁽¹⁶⁾ The mouth of the child should be rinsed by chlorhexidine and kept in contact with the mucosal membrane for at least 30-90 seconds to be effective. For best effectiveness food, drink and mouth rinses should be avoided for at least one hour after use.^(16,18)

Poor oral health has significantly negative effects on systemic health so the pediatric nurse has an important role in providing oral care to children to reduce the impact of oral microbial flora, reduce cancer therapy related to mucositis, maintain nutritional status and to prevent soft tissue infections that may have systemic sequelae^(5,11).

Aim of the work:

The aim of the study is to determine the effect of using chlorhexidine in the prevention of oral lesions in leukemic children receiving chemotherapy.

Research Question

What are the effect of using chlorhexidine in the prevention of oral lesions in leukemic children receiving chemotherapy?.

2. Subjects and Methods

Research design:

It is a quasi-experimental study.

Setting:

The study was conducted at the Haematology Unit in Children's University Hospital at EL-Shatby and at the Oncology Department of Sporting Student's Hospital in Alexandria.

Subjects:

A Convenient sample of 50 children with acute lymphoblastic leukemia were selected according to the following criteria:

- Both sexes
- Free from any other disease.
- Free from any oral lesion.
- Age ranged from 2-16 years.
- Children were taken in the first day of starting chemotherapy either during induction or intensification phase.

The subjects of the study were divided into two groups by simple randomization:-

Group I (Treated group)

It Included 25 children with acute lymphoblastic leukemia who received oral hygiene by 0.1 % of chlorhexidine gluconate when they started chemotherapy.

Group II (Controlled group)

It included 25 children with acute lymphoblastic leukemia who received routine hospital care of oral hygiene.

Tool :It consisted of:

Children's Bio socio-demographic data, such as: name, age, sex, and residence area.

Children's Medical data, such as:

1-Type of ALL:

- B.ALL
- T.ALL

2-Platelet (PLT) count which was classified into:

- Severe thrombocytopenia (PLT < 20.000).
- Moderate thrombocytopenia (PLT 20.000- 40.000).
- Mild thrombocytopenia (PLT > 40.000).⁽¹⁹⁾

3-White blood cells (WBCs) count which was classified into:

- WBCs \geq 50.000.
- WBCs < 50.000.⁽¹⁹⁾

4-Clinical manifestation: Hepatomegaly, Splenomegaly, Hepato- splenomegaly.

5- Protocol of treatment which was classified into high risk and low risk protocol.

-High risk protocol (age 1-9 years with initial WBCS \geq 50.000/u/L or age >10 years and < 21 years with any WBCs count or with T-cell Acute lymphoblastic leukemia (ALL) or with overt testicular leukemia at diagnosis or had center nervous system (CNS) disease at diagnosis).⁽¹⁹⁾

-Low risk protocol (age 1-9.99 years or initial WBCS < 50.000/u/L or with T-ALL are not eligible or with overt testicular leukemia at diagnosis are not eligible or had CNS disease at diagnosis are not eligible).⁽¹⁹⁾

6- Stage of chemotherapy included induction or intensification phase.

• Oral assessment guide (OAG) tool

It was developed by Eilers *et al.*⁽⁹⁾ to assess the condition of oral cavity and the degree of stomatitis for leukemic children.

The tool consists of 8 items: Voice; Swallow.; Lips and angle of the mouth; Tongue; Saliva ; Mucus membrane ; Gingiva and Teeth.

The scoring system of the tool is as follows: Each of the eight items of oral assessment guide is scored as 1, 2 or 3; where:

Score 1 for normal findings.

Score 2 for mild abnormality without compromise of either mucosal integrity or loss of function.

Score 3 for severe abnormality with compromise of either mucosal integrity or loss of function.

Scoring system for assessment of each part of oral cavity:

Score of voice

Communicate with patient and listen whether:

Score 1: The voice is normal.

Score 2: The voice is deep /raspy (hoarse).

Score 3: Patient has difficulty in talking, crying or had painful cry.

Score of swallow reflex

Ask patient to swallow and observe whether:

Score 1: The swallowing is normal.

Score 2: Patient experiences some pain on swallowing.

Score 3: Patient is unable to swallow.

Score of lips

Observe lips and feel tissue, assess whether they are:

Score 1: Smooth, pink, moist.

Score 2: Dry or cracked.

Score 3: Ulcerated or bleeding.

Score of tongue

Observe the tongue and assess whether it is:

Score 1: Pink, moist, and papillae present.

Score 2: Coated or there is loss of papillae with a shiny appearance, with or without redness.

Score 3: Blistered or cracked.

Score of saliva

Insert depressor into mouth, touching the centre of the tongue and the floor of the mouth and observe whether:

Score 1: The saliva is watery.

Score 2: The saliva is thick; or ropy.

Score 3: There is absence of saliva.

Score of mucous membrane

Observe the mucous membrane in the oral cavity and determine if it is:

Score 1: Pink and moist.

Score 2: Reddened or coated (increased whiteness) without ulceration.

Score 3: Ulcerated with or without bleeding.

Score of gingiva (Gums)

Gently press the gums with end of spatula and observe whether:

Score 1: They are pink and firm.

Score 2: They are oedematous with or without redness.

Score 3: There is spontaneous bleeding or bleeding with pressure.

Score of teeth or denture bearing area

Observe the appearance of the teeth or denture bearing area and determine whether:

Score 1: They are clean with no debris.

Score 2: There are plaques or debris in localized area (between teeth if present).

Score 3: There are plaques or debris generalized along gum line or denture bearing area.

The eight subscale scores of oral assessment guide are summed to obtain an overall assessment score that ranging from 8-24.

The total assessment score was categorized as follows:

- If an overall assessment score was 8 or less than 9, it denotes healthy oral cavity.

- If an overall assessment score ranges from 9-16, it denotes moderate mucositis.

- If an overall assessment score ranges from 17-24, it denotes severe mucositis⁽⁷⁾.

Method

1. Official written approval consent for conducting the study was obtained from the responsible administrative personnel.
2. Informed consent was obtained from the parents after explaining the aim of the study.
3. Confidentiality was ascertained.
4. Oral assessment guide tool that was developed by Eilers *et al.* (1988) was adopted.
5. Tool was tested for content validity by 5 experts in the pediatric nursing field and the validity of the tool was 100%.
6. A pilot study was conducted on 5 children with acute lymphoblastic leukemia who received chemotherapy and was satisfying the prescribed criteria to test the clarity and applicability of the tool. These patients were excluded from the studied subjects.
7. The children were divided into two groups by simple randomization: Group I (treated group), and Group II (controlled group).
8. All leukemic children, either treated group or controlled group, were assessed for oral cavity by inspection and digital palpation of the oral mucosa using oral assessment guide (OAG) tool on the first day of starting chemotherapy and after 10 days.
9. Group I (study group) received oral hygiene with 0.1% Chlorhexidine gluconate on the first day of starting chemotherapy 2 times daily in the form of mouth rinse for old children. For young children, it was applied by cotton pad immersed in the used solution for one minute, 30 minutes after breakfast and the second time of mouth

wash 30 minute after the last meal time on the buccal, labial mucosa, lateral surface of the tongue and the soft, hard palate. The children and their mothers were instructed about avoiding food and drink for at least one hour after using mouth wash. This procedure was done every day from the first day of starting chemotherapy and lasted for 10 consecutive days.

10. Group II (controlled group) received routine hospital care of oral hygiene.
11. Evaluation of the degree of stomatitis was categorized according to whether the child had normal oral cavity (scored 8), moderate stomatitis (scored 9-16) or severe stomatitis (scored 17-24).
12. A comparison was done between the two groups, for determining the effect of chlorhexidine gluconate on prevention of oral lesion in oral cavity.
13. The data collection was done during the period from November 2008 to August 2009.

Statistical analysis:

Data were coded and transferred into specially designed formats to be suitable for computer feeding. Following data entry, checking and verification processes were carried out to avoid any errors during data entry. Data were analyzed using a personal computer with statistical package for social sciences (SPSS) version 13.

The following statistical measures were used:

- Descriptive measures included: Percentage, Mean, Standard deviation.
- Chi square test, Fisher's Exact Test, T test was used for test of significance.
- The 0.05 levels was used as the cut off values for statistical significance ($p \leq 0.05$)

3. Results:

Table (I) illustrates the socio demographic characteristics of the studied subjects. 54 % of the subjects was in the preschool age i.e. age 2-6 years, while 20 % of the subjects was in the adolescence age i.e. Age 12-16 years. Moreover, the mean age of the subject was 6.94 ± 4.474 year.

Regarding sex, it was observed from this table that the highest frequencies (66%) of studied subjects were boys, while 34 % were girls.

Concerning the residence, 60 % of the studied subjects were from urban areas and 40 % of them were from rural areas.

Table (II) shows the percentage distribution of the studied subject according to their clinical data. It was found that equal percentage (80%) of studied and controlled groups had leukemia type (B.ALL). As regards clinical manifestation, nearly half of the

studied group (48%) compared to 24% of the controlled group had Hepato-Splenomegaly, While 44% of the controlled group and 24% of the studied group did not suffer from Hepato-splenomegaly. There was no statistically significant difference between the two groups. Concerning platelets (PLT) count, 72 % of the studied group compared to 68% of the controlled group had mild thrombocytopenia. i.e. (PLT count > 40.000). On the other hand, 12% of the studied group compared to 20% of the controlled group had Severe thrombocytopenia (PLT count < 20.000). There was no statistically significant difference between the two groups. The mean of PLT count of the studied and the controlled groups was 132160 ± 131454 and 176800 ± 165293 respectively. No statistically significant difference was found between the means of both groups.

Concerning white blood cells (WBCs) count, equal percentage (92%) of the studied and the controlled groups had WBCs count < 50.000 . The mean WBCs count of studied and controlled groups was 9788 ± 17065 and 9922.4 ± 14963 respectively. There was no statistically significant difference between the mean of both groups.

Regarding protocol of treatment, 64 % of the controlled group and 60% of the studied group received standard risk protocol of treatment. There was no statistically significant difference between both groups. Concerning stage of chemotherapy, equal percentage (68%) was found in the treated and the controlled groups during the induction phase.

As classified in table III which portrayed post 10 days chemotherapy oral assessment categories of studied and controlled groups, it was found that the studied group had more normal oral assessment concerning most of their oral assessment categories than that of the controlled group. As regards voice, the majority of the studied group (96%) had normal voice compared to 68% of the controlled group. On the other hand, none of the studied group had difficulty in talking, crying or had painful cry compared to 20% of the controlled group. Statistically significant difference was found between both groups where $P=0.027$. Concerning swallowing, the majority of the treated group (96%) had normal swallowing compared to 52% of the controlled group. Only 4% of the studied group suffered from some pain during swallowing compared to nearly one third of the controlled group (32%). None of the studied group suffered from the inability to swallow compared to 16% of the controlled group. The difference was statistically significant between both groups where $P=0.002$. Concerning lips, about three quarter of the studied group (76%) had smooth, pink and moist lips compared to 32% of the controlled group. 64% of the controlled group had dry or

cracked lips compared to about one quarter (24%) of the studied group. Statistically significant difference was found between both groups where $P=0.007$.

Regarding tongue, the children who had pink and moist tongue constituted the highest frequency in studied group (92%) while 44% were in the controlled group. Nearly half of the controlled group (52%) had coated tongue or loss of papillae compared to 8% of the studied group. None of the studied group had blistered or cracked tongue compared to 4% of the controlled group. There was statistically significant difference between both groups where $P=0.001$. Regarding saliva, 96% of the studied group had watery saliva compared to 64% of the controlled group. On the other hand, only 4% of the studied group had thick or ropy saliva compared with 36 % of the controlled group. Statistically significant difference was found between the studied and controlled groups where $P=0.004$. Concerning mucous membrane, it was found that the majority of the studied group (88%) and nearly half of the controlled group (48%) had pink and moist mucous membrane. However, 8% of the controlled group had ulcer with or without bleeding in mucous membrane compared to none of the treated group. Statistically significant difference was found between both groups where $P=0.023$. In the gingival of children, the results showed that slightly less than half of the controlled group (48%) had edema with or without redness in gingival, while 16% was found in the studied group. Statistically significant difference was found between both groups where $P=0.02$. Concerning teeth, 20% of the controlled group had plaque or debris in localized area along gum compared to only 4% of the studied group. No statistically significant difference was found between both groups.

Total scores of post 10 days chemotherapy oral assessment of the studied and the controlled groups are presented in table (IV). As classified in this table, nearly three quarters of the studied group (76%) had healthy oral cavity (OAG score=8) compared to 24% of the controlled group. On the other side, 16% of the controlled group had severe mucositis (OAG score from 17-24) compared to none of the treated group. There was statistically significant difference between both groups where $P=0.005$.

Table (V) shows the comparison between the total percent scores of treated and controlled groups regarding oral assessment guide (OAG) following 10 days of chemotherapy and their age. It was observed from this table that three quarters (75%) of children of the treated group whose age ranged from 2-6 years, had healthy oral cavity compared to 20% of the controlled group. None of the treated group whose age ranged from 2-6 years suffered from severe mucositis compared to 6.7% of the controlled group

and there was no statistically significant difference. As Regards children whose age ranged from 6-12 years, it was found that 71.4 of the treated group had healthy oral cavity compared to 16.7% of the controlled group. On the other hand, none of the treated group whose age ranged from 6-12 years suffered from severe mucositis compared to one third (33.3%) of the controlled group and there was no statistically significant difference between them. Regarding children whose age ranged from 12-16 years it was found that the majority (83.3%) of the treated group had healthy oral cavity compared to half (50%) of the controlled group. No one of the treated group whose age ranged from 12-16 years suffered from severe mucositis compared to 25% of the controlled group and there was no statistically significant difference.

Table (VI) reveals the comparison between the total percent scores of treated and controlled groups regarding oral assessment guide (OAG) following 10 days of chemotherapy and their sex. It was found that 70 % of boy of the treated group had healthy oral cavity compared to 46.15 % of the controlled group. No one of the boys of the treated group suffered from severe mucositis compared to 7.7% of the controlled group. There was no statistically significant difference. Regarding girls, all the treated group had healthy oral cavity compared to no one of the controlled group. None of the treated group had severe mucositis compared to 25 % of the controlled group. Statistically significant difference was found between both groups where $P=0.000$.

Table (VII) illustrates the comparison between the total percent scores of treated and controlled groups regarding oral assessment guide (OAG) following 10 days of chemotherapy and their protocol of treatment. It was found that 73.3% of the treated group who received standard risk protocol of treatment had healthy oral cavity compared to 18.8% of the controlled group. However, no one of the studied group who received standard risk protocol of treatment suffered from severe mucositis compared to 18.7% of the controlled group. Statistically significant difference was found between both groups where $P=0.004$. On the other hand, the majority of the studied group (80%) who received high risk protocol of treatment had healthy oral cavity compared to one third (33.3%) of the controlled group, while 20% of the studied group who received high risk protocol of treatment suffered from moderate mucositis compared to more than half (55.6%) of the controlled group. There was no statistically significant difference between both groups.

Table (VIII) clarifies the comparison between the total percent scores of studied and controlled

groups regarding oral assessment guide (OAG) following 10 days of chemotherapy and their stage of chemotherapy. It was found that slightly more than three quarters (76.5%) of the studied group during the induction phase had healthy oral cavity compared to nearly one quarter (23.5%) of the controlled group. No one of the studied group during the induction phase suffered from severe mucositis compared to 23.5% of the controlled group. Statistically significant difference was found between both groups

where $P=0.005$. On the other hand, three quarters (75%) of the studied group, during the intensification phase, had healthy oral cavity compared to only one quarter (25%) of the controlled group. 25% of the studied group, during the intensification phase, suffered from moderate mucositis compared to 75% of the controlled group. Statistically significant difference was found between both groups where $P=0.041$.

Table (I): Bio socio-demographic characteristics of the studied subjects.

Socio-demographic Characteristics	Treated group (N=25)		Controlled group(N=25)		Total

4. Discussion:

Chemotherapy treatment continues to be the mainstay in the treatment of leukemia. but is usually associated with a number of side effects mainly nausea, vomiting, anorexia, alopecia, neuropathy, constipation, hemorrhagic cystitis, moon face, mood changes and mucosal ulceration⁽²⁰⁾.

Oral mucositis (stomatitis) is one of the most debilitating complications following chemotherapy administration. Chemotherapy effects on highly proliferative tissues remain significant. Oral mucositis affects up to 40% of patients undergoing chemotherapy per year in the United States⁽²¹⁾. Mucositis affect all mucous membrane covered surfaces from the mouth to the rectum. It significantly reduces the quality of life and patients' compliance with treatment. Unresolved or untreated mucositis can lead to infections, impaired nutritional status, speech, comfort and other complications that can increase morbidity, and impact patient outcomes. Mucositis is a dose-limiting toxicity for both chemo and radio therapy, and therefore can directly impact survival^(20, 22-25).

The sites of mucositis lesions induced by both radiotherapy and chemotherapy are the non-keratinized mucosa, such as the buccal and labial mucosa, the ventral and lateral surfaces of the tongue, the floor of the mouth, and the soft palate⁽¹⁸⁾.

Oral complications may be prevented by oral assessment prior to the initiation of chemotherapy and then at least daily following the administration of chemotherapy. Adherence to a mouth care protocol and using mouth wash helps to maintain the moisture in the mouth, removes the remaining debris and toothpaste, and reduces the accumulation of plaque and infection⁽¹⁸⁾.

Chlorhexidine gluconate 0.12% is used against candidal and bacterial infection. It inhibits some viruses and it is active against some fungi^(4, 16, 26).

The biological characteristics of the present study reflect that the incidence of leukemia was high in preschool age (Table I). This result was in line with Sherif *et al.*⁽²⁷⁾ who conducted a study about demographic characteristics and history of risk exposure among acute leukaemic children in Alexandria. He reported that most of the acute leukemic children are belonging to the age of 2-5 years. Poncher *et al.*⁽²⁸⁾ who conducted a study about treatment of acute leukemia in children with and without folic acid antagonists also reported that Preschool age children were primarily affected.

It was noticed from the current study that the majority of the studied subjects were boys (Table I). The result was consistent with Jackson *et al.*⁽²⁹⁾ who conducted a study about why acute leukemia is more

common in boys. The finding could be justified by the fact that the presence of a sex responsive gene near to the ABO blood group gene locus on chromosome '9' which relatively protects group O among girls against acute leukemia. The finding of the present study is also supported by many authors who mentioned that acute leukemia occurred more frequently in boys than girls^(4,30). Furthermore, Zorlu *et al.*⁽³¹⁾ who conducted a study about evaluation of risk factors in children with acute lymphoblastic leukemia also reported that the risk of the development of ALL was found to be higher among boys than girls.

The result of the present study revealed that leukemic children from urban areas were more than rural areas (Table I). This result could be attributed to the fact that urban areas are more advanced in using high technology than rural areas. So there was more exposure to chemical substances and X-ray. Accidental exposure to Electro Magnetic Fields (EMF), as X-ray and drug especially during first trimester of pregnancy may be contributing factors to leukemia. This result was in agreement with Freda *et al.*⁽³²⁾ in their study about aggregation of childhood leukemia in geographic areas of Greece. They reported that there was high association between incidences of childhood leukemia and localized environmental exposure in urban areas to a lesser extent in semi urban areas. Tilinca *et al.*⁽³³⁾ who conducted a study about accidental ionizing radiation exposure and its impact on the population also found that incidence of leukemia in urban areas is more than that in rural areas. On contrary to the finding, Koushik⁽³⁴⁾ conducted a study about an ecologic study of childhood leukemia and population mixing in Canada. He found that population growth in rural areas was associated with an increased risk of leukemia particularly for ALL subtype due to population mixing which is not observed in urban areas.

The result of the present study revealed that the majority of the subjects had B.ALL (Table II). This result was in agreement with Magnani *et al.*⁽³⁵⁾ who conducted a study about increasing incidence of childhood leukemia in northwest Italy, and found marked increase in B cells of ALL cases. Rios *et al.*⁽³⁶⁾ also reported B-cell precursor ALL showed high frequency than T lineage ALL.

The current study revealed that the majority of treated and controlled groups had low white blood cells count (Table II). This finding could be explained by the fact that in all types of leukemia the proliferating cells depress bone marrow production of the formed elements of the blood by competing for and depriving the normal cells of the essential

nutrients for metabolism which lead to neutropenia (decrease WBCs counts) resulting in infection.⁽³⁷⁾

The result of the present study showed significantly higher percentage of the treated group having normal post 10 days chemotherapy oral assessment concerning most parts of their oral cavity compared to the controlled group (Table III). These findings could be attributed to using chlorhexidine for the treated group that had the ability to control gingivitis. It was often used as an active ingredient in mouthwash designed to kill dental plaque and other oral bacteria^(38,39). This result is in accord with many authors who reported that there was a significant decrease in the incidence and severity of oral mucositis and ulceration in children who received the preventive oral protocol using 0.12 % chlorhexidine mouth wash compared to the controlled group and reported the value of chlorhexidine mouth rinses in the prophylaxis of oral candidiasis in the myelosuppressed patient^(8,10,13,40,41). Moreover Vickars and Spinelli⁽⁴²⁾ who conducted a study about efficacy of chlorhexidine and nystatin rinses in prevention of oral complications in leukemia mentioned that potential bacterial and fungal pathogens were identified less frequently in the patients using chlorhexidine oral rinse. Contrary to the finding of the present study, Pitten *et al.*⁽⁴³⁾ who conducted a study about whether cancer patients with chemotherapy-induced leukopenia benefit from an antiseptic chlorhexidine-based oral rinse, reported that the chlorhexidine-based product did not provide a clinical benefit for cancer chemotherapy patients. Spijkervet *et al.*⁽⁴⁴⁾ who conducted a study about chlorhexidine inactivation by saliva also reported that chlorhexidine mouth rinsing was of limited value in decontaminating the oral cavity. Furthermore, Wahlin⁽⁴⁵⁾ who conducted a study about effects of chlorhexidine mouth rinse on oral health in patients with acute leukemia reported that there was increase in number of patients who had a burning sensation in the mouth, and a tendency toward increased numbers of salivary enterococci, enterobacteria, and/or *Pseudomonas* in patients who rinsed with chlorhexidine so did not support using of chlorhexidine.

It was noticed that the majority of studied subject had ulcerative lesions present in lips, tongue and mucous membrane as shown in (Table III). Similar to the findings found by Cheng *et al.*⁽⁴⁶⁾ who conducted a study about prevention of oral mucositis in pediatric patients treated with chemotherapy: a randomised crossover trial comparing two protocols of oral care reported that most of the ulcerated lesions were located in the buccal mucosa and labial mucosa.

It was noticed from Table IV that the controlled group significantly had higher percentage of stomatitis

at post 10 days chemotherapy oral assessment compared to treated group (Table IV). This could be attributed to the dual effect of chemotherapy on the oral mucosa; direct and indirect. The direct effect mediated by the treatment-induced stomatotoxicity resulting in mucosal atrophy and the indirect effect is through the systemic effects of chemotherapy, such as bone marrow suppression which affects the severity of oral complications⁽¹¹⁾. This finding was in accord with Pinto *et al.*⁽⁸⁾ who conducted a study about Prevention of oral lesions in children with acute lymphoblastic leukemia and reported that there was a high frequency of mucositis in children with ALL who did not receive chlorhexidine.

Concerning the degree of stomatitis, it was found that the children who used chlorhexidine had healthy oral cavity. 24% of treated group suffered from moderate oral mucositis and no one suffered from severe oral mucositis (Table IV). This might be attributed to the fact that the chlorhexidine had the ability to control, prevent, kill dental plaque and other oral bacteria⁽⁴⁾. Many authors were in line with the results of the present study who reported that chlorhexidine mouth rinse significantly reduced the incidence of oral mucositis in the treated group and the severity of oral mucositis was less compared to control group^(10,40,47). Moreover, Cheng *et al.*⁽⁴⁶⁾ cited that on their study about the prevention of oral mucositis in pediatric patients treated with chemotherapy: a randomized crossover trial comparing two protocols of oral care, also reported that OAG scores for mucositis in patient who use chlorhexidine was 8-13 (moderate mucositis).

The present study revealed that the majority (73.9%) of children of controlled group developed moderate and severe mucositis during neutropenia compared to 26.1% of treated group who developed moderate oral mucositis (Table VII). This result was in harmony with Cheng *et al.*⁽¹⁰⁾ who performed a study about evaluation of an oral care protocol intervention in the prevention of chemotherapy-induced oral mucositis in pediatric cancer patients. The study revealed that the majority of the children of controlled group during neutropenia developed oral ulcerative lesions and only one third of the subjects using the oral care protocol (chlorhexidine mouth rinse and 0.9% saline rinse) developed oral ulcerative lesions.

Conclusion

Based on the findings of the present study, it was concluded that Chlorhexidine was an effective solution in preventing and decreasing oral mucositis and gingivitis (swelling, redness, and bleeding of the gums) in leukemic children receiving chemotherapy. However, children in the treated group had healthier

oral cavity and lowest moderate degree of oral mucositis and no one of them developed severe oral mucositis compared to children in controlled group following 10 days of chemotherapy administration and significant differences were illustrated.

Recommendations

- Based on the findings of the present study the following recommendations are suggested:
- Responsibility of the nurses toward all children being treated from leukaemia and receiving chemotherapy is preventing and decreasing oral complication of chemotherapy through assessing oral cavity by using standardized grading system as an oral assessment guide (OAG) tool prior to the initiation of chemotherapy and at least daily following the administration of it.
- Creating an oral care plan to each child individually involving cleaning the teeth by using a mouth wash with Chlorhexidine gluconate is an important recommendation in preventing oral complications and decreasing severity of oral mucositis and treating gingivitis (swelling, redness and bleeding of the gums).
- Leukemic children receiving chemotherapy and their mothers should be informed about the possible oral complications of chemotherapy, how to detect and decrease the incidence of mucositis, and how to maintain oral hygiene.
- Direct family involvement in children oral care should be encouraged for maximum treatment compliance of their leukemic children.

Posttraumatic Stress among Undergraduate Emergency Nursing Students

Hayam I. A. Asfour¹ and Fatma Hussein Ramadan^{*2}

¹Critical Care & Emergency Nursing Department, Faculty of Nursing, University of Alexandria.

²Psychiatry Nursing and Mental Health Department, Faculty of Nursing, University of Alexandria.

fatma_ramadan45@yahoo.com

Abstract: Undergraduate emergency nursing students are often exposed to stress when helping patients in emergency situations. Emergency nursing students are vulnerable to the development of symptoms of post-traumatic stress Disorder (PTSD). Stress reactions among helpers can be regarded as a natural behavior and reaction when experiencing a traumatizing event and by the stress resulting from helping or wanting to help a traumatized or distressed person. Any trauma exposure can trigger post traumatic stress disorder. Selley reiterates that health workers as well as primary victims are at risk of developing PTSD. The aim of this study was to examine posttraumatic stress among undergraduate emergency nursing students. Methods: The sample of this study consisted of 250 undergraduate students attended and studied emergency nursing course during the period from February till May 2009. Two instruments were used to measure reactions to traumatic events, Impact of Event Scale Revised (IES-R) and the Post Traumatic Symptom Scale (PTSDS). Results: Of those who reported a traumatic situation the majority of them scored 30 or more on the IES-R subscale. Scores over 30 indicate a stress reaction with certain likelihood of post-traumatic disorder. On the PTSDS-subscale the majority of students scored 5 or more, which indicates a relative strong reaction. Conclusion: The high prevalence of post-traumatic stress in undergraduate emergency nursing students indicates an inability to cope with stress in daily life.

Keywords: Posttraumatic Stress; Undergraduate; Emergency; Nursing; Student

1. Introduction:

The way in which stress is experienced by students in higher education has

been a topic which has raised increasing interest, leading to the need of identifying stressors and their consequences on students' health and well-being. Stress is defined as the physiological, psychological and behavioral response of an individual attempting to adapt to internal and external pressure^[1, 2]. Researchers have found that the perception of high stress levels in students can lead to poor academic performance, depression, attrition and serious health problems. Nursing students have higher perceived stress levels than the general student population^[2,3]. It has been widely recognized by those engaged in nursing education that clinical practice is a significant and essential part of a student nurses' education. The clinical setting is fundamental to the nursing students learning because it offers opportunities for them to work with 'real' patients with real problems. It is commonly accepted that nursing profession by its nature, place personnel at risk of experiencing critical incidents^[4,5]. One of the nursing specialties that considered as most stressful is emergency nursing.

Emergency nursing is a specialty area of the nursing profession that deals with human responses to any trauma or sudden illness and requires immediate intervention to prevent imminent severe

damage or death. Undergraduate emergency nursing students are often exposed to traumatic stress when helping patients in emergency situations. Emergency nursing students face many challenges on a day to day basis; seeing victims of shooting and stabbing; persons who are burned or beaten, accident victims, and every conceivable acute cardiac emergency and serious illness. These stressful situations let nursing students to report the resurgence of painful life events or symptoms of psychological injury when learning about or witnessing critical symptoms^[6-8].

Any event which is outside of the realm of normal human experience and very distressing is considered a traumatic stressor or critical incident. Such events usually involve a perceived threat to the physical integrity of the individual and evoke reactions of intense fear, horror and/or helplessness. In times of stress, a student normally engages in certain coping strategies to handle the stressful situations and the associated emotions. The more an individual adopts adaptive coping strategies, the less his/her stress, and better his/her mental health^[2]. Psychological and behavioral responses of persons after exposure to a traumatic situation may be no reaction, a normal stress response, psychological and behavioral syndrome or may lead to psychological disorders. If unmanaged, approximately 22% of persons who experience critical incident stress will still be symptomatic for 6 - 12 months after the event

and approximately 4% will be at risk for developing post-traumatic stress disorder (PTSD)^[9].

Posttraumatic stress disorder (PTSD) is an anxiety disorder. Anxiety is derived from the Greek root meaning "to press tight". It is generally considered a healthy adaptive response to stress, anxiety is experienced by all individuals during their life and follows fear, threat, danger, and/or the absence of an environment that signifies safety. In the *Diagnostic and Statistical Manual of Mental Disorders*^[1], the criteria for diagnosis of PTSD are defined as (1) exposure to a traumatic event, with a response including fear, helplessness, or horror; (2) reexperiencing the event in a variety of subjective experiences that may include intrusive recollections of the event and psychological distress; (3) persistent avoidance of stimuli associated with the trauma accompanied by 3 or more of the following symptoms: avoidance of emotions and activities that arouse recollections of the event, memory impairment related to the event, diminished interests, detachment, restricted affect, and unrealistic perception of the future; and (4) increased level of arousal evidenced by symptoms that include sleep disturbance, startle response, emotional instability, hypervigilance, and difficulties in concentration. These criteria and symptoms are then classified as affecting a person by impairing the person's level of function.. PTSD is considered acute if symptoms persist for at least 1 month and is classified as chronic if symptoms persist longer than 3 months^[10].

The lifetime prevalence of PTSD is 1%-3% in the general population, 15%-20% in emergency response personnel, nursing and 26%-30% in Vietnam War Veterans,^[9] Selley reiterates that health workers as well as primary victims are at risk of developing PTSD. Hamaideh & Ammouri,^[11] found that nurses experience high levels of job stressors in highly stressful areas of work such as Intensive Care Units. Clinical experience in such stressful area is one of the most anxiety producing components of the nursing program which has been identified by nursing students^[11]. Nursing programs have one of the highest dropout rates because of burnout. Students who cannot handle the stress often become exhausted and quit^[12]. Untreated PTSD is disabling, and firm recommendations exist for early treatment to prevent reduction in the quality of life. Therefore, the aim of this study was to examine posttraumatic stress among undergraduate emergency nursing students.

The aim of this work

The aim of the work is to examine posttraumatic stress among undergraduate emergency nursing students.

Research questions:

- 1- What are the most perceived stressful events among undergraduate emergency nursing students?
- 2- What are the post-traumatic symptoms experienced by emergency nursing students during their clinical experiences?

2. Materials and Methods:

Study design:

A descriptive design was used in this study.

Setting:

The study was conducted at the Faculty of Nursing, Alexandria University, at Critical Care & Emergency Nursing Department.

Subject:

All undergraduate nursing students (250) who attending and studying emergency nursing course were included during the period from February till May 2009. All students were studying the emergency nursing course for the first time and had no experience in caring for emergency or critically ill patients. Also, they were trained in the same clinical areas during their studying of emergency nursing course.

Tool:

The tool used in this study was "Post-traumatic Stress among Undergraduate Emergency Nursing Students structured interview schedule"
"This tool consisted of three parts:

The first part of the tool is the Impact of Event Scale Revised (IES-R). The IES-R is a self-administered, 22-item questionnaire based on three clusters of symptoms identified in the Diagnostic and Statistical Manual of Mental Disorders, third edition (DSM-III), as indicators of posttraumatic stress disorder (PTSD). Intrusion is assessed with eight items on the scale. Avoidance is assessed with eight items on the scale. Hyperarousal is assessed with six items on the scale. The IES-R is used widely to evaluate acute stress symptoms, and post-traumatic symptoms. This scale is based on the Horowitz *et al.*,^[1] original Impact of Event Scale (IES),^[9-13, 20]

The original IES consisted of items used to assess only two of the three symptom categories of PTSD (re-experience and avoidance) and, thus, while valid for use in assessing post-traumatic stress symptoms, it was not a valid measure of PTSD because it did not assess hyperarousal symptoms that are included in the most recent diagnosis criteria.13 Subsequently, the IES was revised (IES-R) and now comprises 22 items covering three symptom categories including eight re-experience/intrusion

items, eight avoidance items, and six hyperarousal items.

The IES-R is not a diagnostic or screening tool for PTSD; rather, it relies on a patient's own report of symptoms and is used to gauge response no sooner than two weeks after a traumatic event, as well as to evaluate recovery. It is used to rate the severity of intrusion (dreams about the event), avoidance and numbing (effort to avoid reminders of the event), and hyperarousal symptoms (feeling watchful and on guard as anger, irritability, hypervigilance, difficulty concentrating,) on a five-point severity scale (0 = not at all; 4 = extremely; $\alpha = 0.92$). The total score is the sum of all items (range 0 --88). Total scores >30 indicate the existence of a clinical level of distress.

The second part of the tool is the Post Traumatic Stress Syndrome Questions Inventory (PTSS), a self-report scale based on the Diagnostic and Statistical Manual for PTSD^[7,21]. This questionnaire is commonly used in a variety of patient populations and has excellent sensitivity and specificity for PTSD. The PTSS-10 is a questionnaire assessing 10 common symptoms of PTSD. The measure range is from 1 point (none) to 7 points (always). The total score ranges from 10 to 70, with higher scores indicating more symptoms; A total score of greater than 35 is associated with a high probability that the person fulfills the diagnostic criteria for PTSD^[7, 21].

In addition to the data regarding demographic factors and students characteristics, including age, sex, clinical trauma experience and students' descriptions of a traumatic event will be obtained.

Methods:

Official permission to conduct the study was obtained from the head of Critical Care & Emergency Nursing Department. The content validity of the tool was tested by experts in the field of critical care and nursing education and necessary modifications were done. Internal consistency of the subscales of IES-R (The first part of the tool) was calculated using Cronbach's Alpha. It was found to be consistent (intrusion = 0.86, avoidance = 0.92, hyperarousal = 0.83). The reliability of the PTSS- 10 {the second part of the tool} was measured (Cronbach alpha was 0.92), indicating a high internal consistency and the test-retest reliability provided good support for the internal consistency and stability (test retest reliability, $r = 0.89$). Explanation of the aim of the study for students was done and the written consent to participate in the study was obtained. The anonymity and confidentiality of responses, voluntary participation and right to refuse to participate in the study were emphasized to students.

A pilot study was carried out on a sample of ten students who were selected randomly to ascertain the clarity and applicability of the tool and the necessary modifications were done. The students were classified into ten groups each group contains 25 students and it was interviewed once by the researcher using the tool. Each interview lasted from 1 to 2 hours.

Statistical analysis:

The raw data were coded and transformed into coding sheets. The results were checked. Then, the data were entered into SPSS system files (SPSS package version 13) using personal computer. Output drafts were checked against the revised coded data for typing and spelling mistakes. Finally, analysis and interpretation of data were conducted.

The following statistical measures were used:

- Numbers and percentage: used for describing and summarizing quantitative data.
- Range, arithmetic mean (X) and standard deviation (SD) used for normally distributed quantitative data.
- P value of 0.05 was used to assess the significance of the result.
- Statistical tests used in the present study were Student t- test was used for comparing between two means

3. Results:

The majority of the students were females (75.6%) and less than 20 years old (67.2%). Table (1) shows the students' descriptions of the most stressful events in their clinical experience which include : seeing patients die (43.2%), stress related to feeling overworked (42.8%), trauma-related injuries (36.4%) performing cardiopulmonary resuscitation (30.4%), and feeling unable to save a specific patient (28%). Table (2) reveals that nearly two thirds of the emergency nursing students (60%) had high level of post traumatic stress {Impact of Event Scale Revised (IES-R)} with Mean \pm SD {47.00 \pm 11.31} which indicated the existence of a clinical high level of distress. More than half of the emergency nursing students (56.4%) had high level of hyperarousal symptoms, nearly half of them had high level of avoidance and intrusion symptoms (48.8 & 46.4, respectively). Table (3) illustrates that female students experienced a higher level of stress symptoms than male students and a statistically significant relation was found between sex and intrusion, avoidance, hyperarousal, and the total score of stress symptoms ($\chi^2=23.212$ & $t= 5.481$, $\chi^2= 0.051$ & $t= 0.598$, $\chi^2= 6.705$ & $t= 3.234$ and $\chi^2=12.417$ & $t= 4.038$ respectively). Table (4) reveals that Less than half of the students (43.3%) who

experienced high level of stress symptoms were in the age of 20 years or less with a statistically significant relation was found between age and total score of stress symptoms ($t=2.099^*$, $p=0.037$). Table (5) shows that students had score in Post Traumatic Stress Syndrome Questions Inventory (PTSS) as follows low score 56.4%, moderate score 4.0 % and high score 39.6 % respectively. In addition , Table(6) shows that more than one third of female students

(34%) fulfill the diagnostic criteria for PTSD in a higher level than male students (5.6%) with a statistically significant difference was found between sex and (PTSS) ($\chi^2= 11.942$ at $p= 0.003$ and $t= 4.223$ at $p <0.001$ respectively). Concerning the relation between age and (PTSS), table (7) illustrates that there was no statistically significant relation was found ($t=0.150$, $p=0.881$).

Table (1): Distribution of students according to their description of traumatic event.

Descriptions traumatic event	No.	%
Seeing patients die	108	43.2
Open wounds	33	13.2
Massive bleeding	35	14.0
Trauma-related injuries	91	36.4
Performing “futile” care to patients	57	22.8
Performing cardiopulmonary resuscitation	76	30.4
Stress related to feeling overworked	107	42.8
Stress related to not being able to save a specific patient	70	28.0
Verbal abuse from family members	12	4.8
Verbal abuse from other nurses	1	0.4

Table (2): Distribution of the students according to their level of post-traumatic symptoms using Impact of Event Scale Revised (IES-R)

4. Discussion

Nursing is generally considered a stressful profession. Nurses by virtue of their work may be occasionally or routinely exposed to stressful and sometimes traumatic situations in their work especially in emergency care .Within emergency care context, traumatic incidents may include situations such as being threatened or assaulted, witnessing an

assault, being held hostage or providing care in the wake of a disaster. Individual nurses may exhibit symptoms similar in both nature and severity to PTSD after repeated exposure to these stressful situations^[11]. Nursing students who attend emergency nursing specialty also facing various kinds of stressors such as workload, inadequate preparation, and dealing with issues of death and

dying. Besides, they exposed to various academic stressors as other college students such as midterm and final examinations, paper works and assignments. Exposure to a traumatic incidents will inevitably leads to psychological complications such as post traumatic stress, anxiety and depressive disorders. These complications may persist for years after the original trauma and resurface in response to other stressful situations. High stress levels in nursing students may affect memory, concentration, and problem-solving ability. It may lead to poor academic performance and scholastic achievement^[2,3].

In the current study, it was noted that the emergency nursing undergraduate students face a lot of academic stressors, as they described that the most stressful events in their experience are seeing patients die, stress related to feeling overworked and trauma-related injuries. This result is supported by Walton^[6], Seyedfatemi *et al.*,^[2] and Burnard *et al.*,^[13] who found that the most frequent academic source of stress was "increased class workload" and the most frequent environmental sources of stress were being "placed in unfamiliar situations which indicate the existence of a high clinical level of distress. Students have a large amount of preparatory work during their clinical training. As in their clinical rotations, students must exhibit a high level of responsibility and accountability in dealing with patients. Students often perform procedure that can cause serious harm to their patients and fear making a mistake. They use highly technical equipment. Time management can be a pressure as they have many tasks that must be accomplished in a short period of time. They deal with patients that are seriously ill or often dying.

The results of the current study revealed that students have high level of stress symptoms and this can be explained that the emergency nursing students have had specialized education, training, and experience to gain expertise in assessing and identifying patients' health care problems in crisis situations. In addition, the emergency nurse establishes priorities, monitors and continuously assesses acutely ill and injured patients, supports and attends to families, supervises allied health personnel, and teaches patients and families within a time limited, high-pressured care environment. This is in line with many studies which indicate that nursing students may be more prone to stress during their clinical practice in highly stressful specialties such as ICUs, ER, OR, and Psychiatric Units than other students^[11,12]. Emergency nursing students ranked coping with 'death and dying' more highly as a source of distress than did those in other specialties^[12-14].

In the present study, many of the items ranked as stressful by the nursing students were also identified by other populations, such as amount of

material to learn, examinations and lack of timely feedback from faculty. In addition, the nursing students identified feelings of inadequacy in dealing with acutely ill patients. This is in line with Jonsson *et al.*,^[7] who studied post-traumatic stress among Swedish ambulance personnel and reported their scores 31 or more on the IES-15 subscale. Scores over 31 indicate a stress reaction with certain likelihood of post-traumatic disorder^[7].

In the present study, more than half of students had low (PTSS) score and more than thirty had high (PTSS) score. The low score of (PTSS) among nursing students could possibly be explained in several ways. The fact that they are most of the time under close observation & supervision and support from their clinical instructors in the clinical areas. Regarding the high score of (PTSS) for some students, this can be due to the presence of individual differences among nursing students, students are different in their identification of stressors especially with the complex and frequently changing healthcare environment such as Intensive Care Units and Emergency Departments. The variation between individuals in term of the perceptions of stress is most likely to arise from differences in personal factors as the ability to cope and levels of companionship during clinical practice. Because personal factors influence the perceptions of stress, it is important for the emergency nursing educators to consider how emergency nursing students might be supported, and what are the most effective coping strategies that should be utilized to overcome or decrease the stress levels of these students.

In the current study, the score of (IES-R) differs according to students' gender, PTSD is significantly higher in female than in male students. This is in agreement with Girard *et al.*,^[15] who found that women were significantly more likely than men to have high levels of PTSD symptoms after critical illness. Several studies have demonstrated that women are more vulnerable to PTSD, even after controlling for differences in the type of trauma, and a higher incidence of pre-existing anxiety and/or depression disorders is postulated to play some role in the difference in PTSD rates between the sexes^[16-18].

In the present findings, the rates of PTSD symptoms are most prevalent in younger age students. It may be attributed to students' lack of experience to cope with stressful situations in the emergency clinical setting. On the same line, Eckardt,^[19] found that the prevalence of post-traumatic stress disorder was high in younger age because they tend to be more exposed to precipitating situations.

Conclusion:

It is obvious from these findings that the emergency nursing students are exposed to a variety of stressors and suffer from PTSS. Also, This study Provides evidence for nursing educators that helping students to overcome stress during their emergency clinical practice is important.

Recommendations:

Orientation programs for first-year students should include stress management as a topic of discussion, workshops on stress and strategies to cope with stress. Such workshops might also be conducted during the academic year. Counseling center should introduce effective coping strategies through counseling programs for new students and support at risk students during their clinical practice. The availability of student counseling service, peer learners, and preceptor-ship may be helpful for increasing adaptive coping and decreasing stress. Students should be informed of the presence of counseling center and counseling team in the faculty. Clinical instructors should discuss with the emergency nursing students the most commonly identified sources of stress. The training in emergency nursing specialty should be postponed to the fourth year. Faculty administrators should consider incorporating stress management training into orientation activities for nursing students.

Prevalence and Outcome of Acute Kidney Injury in the intensive care unit according to RIFLE criteria: A single-center study

Mohamed Fouad* and Mabrouk I. Ismail

Nephrology unit, Internal Medicine Department, Zagazig University Hospital, Zagazig, Egypt
[*Dr.M.Fouad@hotmail.com](mailto:Dr.M.Fouad@hotmail.com)

Abstract: Acute kidney injury (AKI) is common in the intensive care unit (ICU) and is associated with significant morbidity and mortality. This requires clinicians to be familiar with recent advances in definitions, diagnosis, prevention, and management of AKI in the ICU. The Acute Dialysis Quality Initiative (ADQI) represents the efforts of a workgroup seeking to develop consensus and evidence-based statements in the field of AKI. The ADQI group proposed a consensus graded definition, called the RIFLE criteria (Risk, Injury, Failure, Loss, and End stage). Objective: To estimate the prevalence of AKI in ICU and assess the ability of the RIFLE criteria to predict the outcome of AKI in ICU. Methods: We performed a retrospective cohort study in the internal medicine ICU, Zagazig University Hospital, in the period from January 2010 to December 2010. We excluded patients younger than 15 years, patients receiving chronic hemodialysis admitted to ICU, kidney transplant patients, length of hospital stays were <24 hours, or readmitted to the ICU during the study period. RIFLE criteria classified AKI patients into three stages of increasing severity Risk(R), Injury (I), and Failure (F). The outcomes of AKI patients in ICU were recovery, kidney loss, end stage renal disease (ESRD) or death. Results: The total number of ICU admissions during the study period was 8304 patients. After application of exclusion criteria, the number of the study became 5440 patients. According to RIFLE criteria 1885 (34.65%) had AKI. RIFLE criteria classified them into Risk 13.32%, Injury 11.91% and Failure 9.41%. The crude outcome of AKI patients as follow 77.24% recovered, 9% lost kidney functions and required renal replacement therapy (RRT), and 2.28% reached ESRD. The crude mortality of AKI patients was 20.47% versus 7.76% mortality in patients without AKI. The hospital recovery stratified by RIFLE criteria decreased with worsening RIFLE classes (R, I, F) 84.27%, 79.62% and 64.25% respectively. Patients' lost kidney functions and required RRT stratified by RIFLE criteria increased with worsening RIFLE classes 5.79%, 7.4% and 15.62% respectively. Patients reached ESRD stratified by RIFLE criteria increased with worsening RIFLE classes 1.2%, 2% and 4.1% respectively. The hospital mortality AKI patients stratified by RIFLE criteria increased with worsening RIFLE classes 14.48%, 18.36% and 31.64% respectively. The urinary output (UOP) criteria associated with lower mortality and higher recovery rate than creatinine criteria. Conclusion: The prevalence of AKI in the internal medicine ICU, Zagazig University Hospital according to RIFLE criteria is 34.65%. RIFLE criteria are useful in predicting the outcome of AKI patients.

[Mohamed Fouad and Mabrouk I. Ismail. Prevalence and Outcome of Acute Kidney Injury in the intensive care unit according to RIFLE criteria: A single-center study. Journal of American Science 2011; 7(6):1005-1012].(ISSN: 1545-1003). <http://www.americanscience.org>.

Keywords: Prevalence; Acute Kidney Injury; intensive care unit; RIFLE criteria

1. Introduction:

Acute renal failure (ARF) has traditionally been defined as abrupt loss of kidney function that results in the retention of urea and other nitrogenous waste products and dysregulation of extracellular volume and electrolytes. The loss of kidney function is most easily detected by measurement of the serum creatinine (SCr) which is used to estimate the glomerular filtration rate (GFR) [1] ARF now increasingly referred to as AKI [2]. The Acute Dialysis Quality Initiative convened in 2002 and proposed the RIFLE classification specifically for AKI in critically ill patients [3]. The most severe classification met by either criterion should be used. Of note, patients with primary kidney diseases such as glomerulonephritis were excluded from this definition [4]. The RIFLE classification is comprised

of three stages of increasing severity, which correspond to risk (stage 1), injury (stage 2), and failure (stage 3). Loss and ESRD are removed from the staging system and defined as outcomes [5].

The cause of AKI in the ICU is commonly multi-factorial and frequently develops from a combination of hypovolemia, sepsis, medications, and hemodynamic perturbations. It is frequently not possible to isolate a single cause, thereby further complicating search for effective interventions in this complex disease process [6]. Sepsis is most common cause of AKI in a general ICU, accounting for up to 50% of cases [7], medications are also common cause of AKI [8]. Nearly all cases of ICU-associated AKI result from more than a single insult [9].

In the critically ill patient, the first kidney insult is often not predictable, therefore prevention of AKI

in the ICU often means prevention of a secondary insult in an at-risk patient [10]. Previous intervention and treatment trials have not had any significant impact on overall outcomes of patients with AKI [5], while in parallel; there is growing recognition of the strong association between the severity of AKI and subsequent morbidity and mortality, as well as costs during hospitalization [11] and in the longer term following hospital discharge [12].

AKI is a common clinical problem in ICU patients and typically portends an increase in morbidity and mortality [13]. AKI occurs in approximately 7% of all hospitalized patients [14] and in up to 36% to 67% of critically ill patients depending on the definition used [9]. Based on 75,000 critically ill adults, more severe AKI occurs in 4% to 25% of all ICU admissions [15]. On average, 5% to 6% of ICU patients with AKI require renal replacement therapy RRT [16]. The true incidence of ESRD after AKI is unknown because epidemiologic studies do not routinely or consistently report rates of renal recovery [17].

Morbidity, a less appreciated consequence of AKI in the ICU, is associated with increased cost [11], increased length of stay [18] and increased risk of ESRD [19].

Reported mortality in ICU patients with AKI varies considerably between studies depending on AKI definition and the patient population studied. In the majority of studies, mortality increases proportionately with increasing severity of AKI [20]. In patients with severe AKI requiring RRT, mortality is approximately 50% to 70% [21]. In a UK-based study, overall survival in 1,095 patients with severe AKI (serum creatinine >6.7 mg/dl) was 59%. Of these 16% remained on long-term dialysis [22]. In the French study, the mortality was 58%, and among the survivors, mean serum creatinine was 2.6 mg/dl at the time of discharge from ICU [23].

While AKI requiring RRT in the ICU is a well-recognized independent risk factor for in-hospital mortality [11], even small changes in SCr are associated with increased mortality [24]. There is no current consensus on the indications for RRT in AKI. The only absolute indications for RRT in critically ill patients are metabolic acidosis, hypervolemia, and hyperkalemia that do not respond to other forms of therapy, although the early initiation of RRT might be beneficial in theory, data guiding the optimal timing of dialysis in patients with ARF is scarce [25]. We sought to estimate the prevalence of AKI in ICU and assess the ability of the RIFLE criteria to predict outcome in those patients.

2. Patients and Methods:

We constructed a retrospective cohort study on all adult hospitalizations during a 12 month in the period from January 2010 to 31 December 2010, at the internal medicine ICU of Zagazig University Hospital. All admitted patients were screened using the computerized hospital admissions and discharges database.

Exclusion criteria: Patients receiving chronic hemodialysis admitted to ICU or who had a kidney transplant, patients younger than 15 years, or if their length of hospital stays were <24 hours, and we only considered the first admission for patients who were readmitted to the ICU during the study period.

Demographic information: Collected from the database (age, gender, dates and source of admission, type of admission, intensive care unit admission, and hospital mortality).

Recording data: Primary diagnosis, presence of co morbidities, and need for mechanical ventilation. Physiologic data included Glasgow Coma Scale (GCS), vital signs, PaO₂/FiO₂ ratio, pH and serum electrolytes. Urine output was recorded at least once every one hour, and serum creatinine was measured at least once daily.

The RIFLE criteria diagnosed and classified our patients into [3]

RIFLE	SCr Criteria	UOP Criteria
Risk	1.5-fold increase in the SCr or *GFR decrease by 25%	<0.5 mL/kg per hour for 6 hours.
Injury	Twofold increase in the SCr or GFR decrease by 50 %	<0.5 mL/kg per hour for 12 hours.
Failure	Threefold increase in the SCr or GFR decrease by 75 %	<0.5 mL/kg per hour for 24 hours, or anuria for 12 hours.
Loss	Complete loss of kidney function (e.g., need for RRT) for > 4 weeks.	
ESRD	Complete loss of kidney function (e.g., need for RRT) for > 3 months.	

*GFR was measured by Cockcroft-Gault formula: creatinine clearance (mL/min) = [(140 - age) × weight (kg)] / [72 × serum creatinine (mg/dL)] (×0.85 for women).

Prognosis of AKI:

1. Renal Recovery, either.

Complete renal recovery: Return of renal function to baseline

Partial renal recovery: Persistent change in RIFLE classification but not persistent need for RRT

2. Kidney loss:

3. ESRD:

4. Mortality: patients who died during the study.

The total numbers of ICU admissions during the study period were 8304 patients.

After application of exclusion criteria, the total number of the study became 5440 patients.

RIFLE criteria identified 1885 from studied patients suffered from AKI in different grades.

Their mean age was 56.02±13.7 (18-88) years.

Their gender 1035 "55 %" males and 850 "45 %" females

Time of AKI diagnosis: 55% of AKI patients were diagnosed on the day of admission and 45% developed AKI later during the periods of staying in ICU.

Co morbid disease: 575 (30.5%) from all AKI patients associated with other co morbid disease

Each of the severity classes (R, I, F) was reevaluated according to UOP criteria or SCr criteria and we choose the most severe classification met by either criterion

RIFLE criteria, classified AKI patients into Risk 725 patients (485 defined by SCr criteria and 240 defined by UOP criteria), Injury 648 patients (388 defined by SCr criteria and 260 defined by UOP criteria) and Failure 512 patients (308 defined by SCr criteria and 204 defined by UOP criteria)

Recorded hospital mortality in non AKI patients was 276 =7.76%.

Statistical Analysis

Data were collected, entered and checked to an SPSS version 15. Data were expressed as mean ± standard deviation and Chi square (χ^2) test was used for qualitative data to test the association between a factor exposure and outcome and Z test (test of proportion) was used for comparison of two proportions [26].

*P value of <0.05 was considered significant

3. Results:

The actual studied number was 5440 patients RIFLE criteria identified 1885 patients from a studied number suffered from AKI in different grades, so the prevalence of AKI in the ICU was 34.65%.

RIFLE criteria classified ICU patients into Risk 725 (13.32%), Injury 648 (11.91%) and Failure 512 (9.41%).

The crude outcome of AKI patients in our ICU: (Table 1)

The crude total recovery of all AKI patients 77.24%

The crude total lost kidney functions and required RRT of all AKI patients 9%

The crude ESRD of all AKI patients 2.28%

The crude mortality of all AKI patients 20.47%

Table (1): The crude outcome of AKI patients

	No	%
AKI patients	1885	= 34.65%
Recovery	1456	= 77.24%
Kidney loss "RRT"	170	= 9%
ESRD	43	= 2.28%
Mortality	386	= 20.47%

Natural history and Clinical outcomes stratified by RIFLE category: Figure (1)

Risk category: From 725 patients 165 patients initially recovered and the total end recovery 611 (84.27%) patients. 455 (62.75%) patients progressed to the next stages, most of them recovered later, 42 (5.79%) patients lost kidney functions and required RRT and 9 (1.2%) patients reached ESRD. The remaining 105 (14.48%) patients died.

Injury category: From 648 patients 246 patients initially recovered and the total end recovery 516 (79.62%) patients. 285 (43.98%) patients progressed to the next stages, most of them recovered later, 48 (7.4%) patients lost kidney functions and required RRT and 13 (2%) patients reached ESRD. The remaining 119 (18.36%) patients died.

Failure category: From 512 patients 270 patients initially recovered and the total end recovery 329 (64.25%) patients. 80 (15.62%) patients lost kidney functions and required RRT and 21 (4.1%) patients reached ESRD. The remaining 162 (31.64%) patients died.

Outcome comparison between RIFLE classes Table (2)**Recovery:**

The recovery stratified by RIFLE criteria showed statistically significantly decrease with worsening RIFLE classes .P<0.001

Lost kidney function and RRT

Patients lost kidney functions and required RRT stratified by RIFLE criteria showed statistically significantly increase with worsening RIFLE classes. P<0.001

Patients end by ESRD

Patients reached ESRD stratified by RIFLE criteria showed statistically significantly increase with worsening RIFLE classes. P=0.003

Mortality:

The hospital mortality of AKI patients stratified by RIFLE criteria showed statistically significantly increase with worsening RIFLE classes .P<0.001

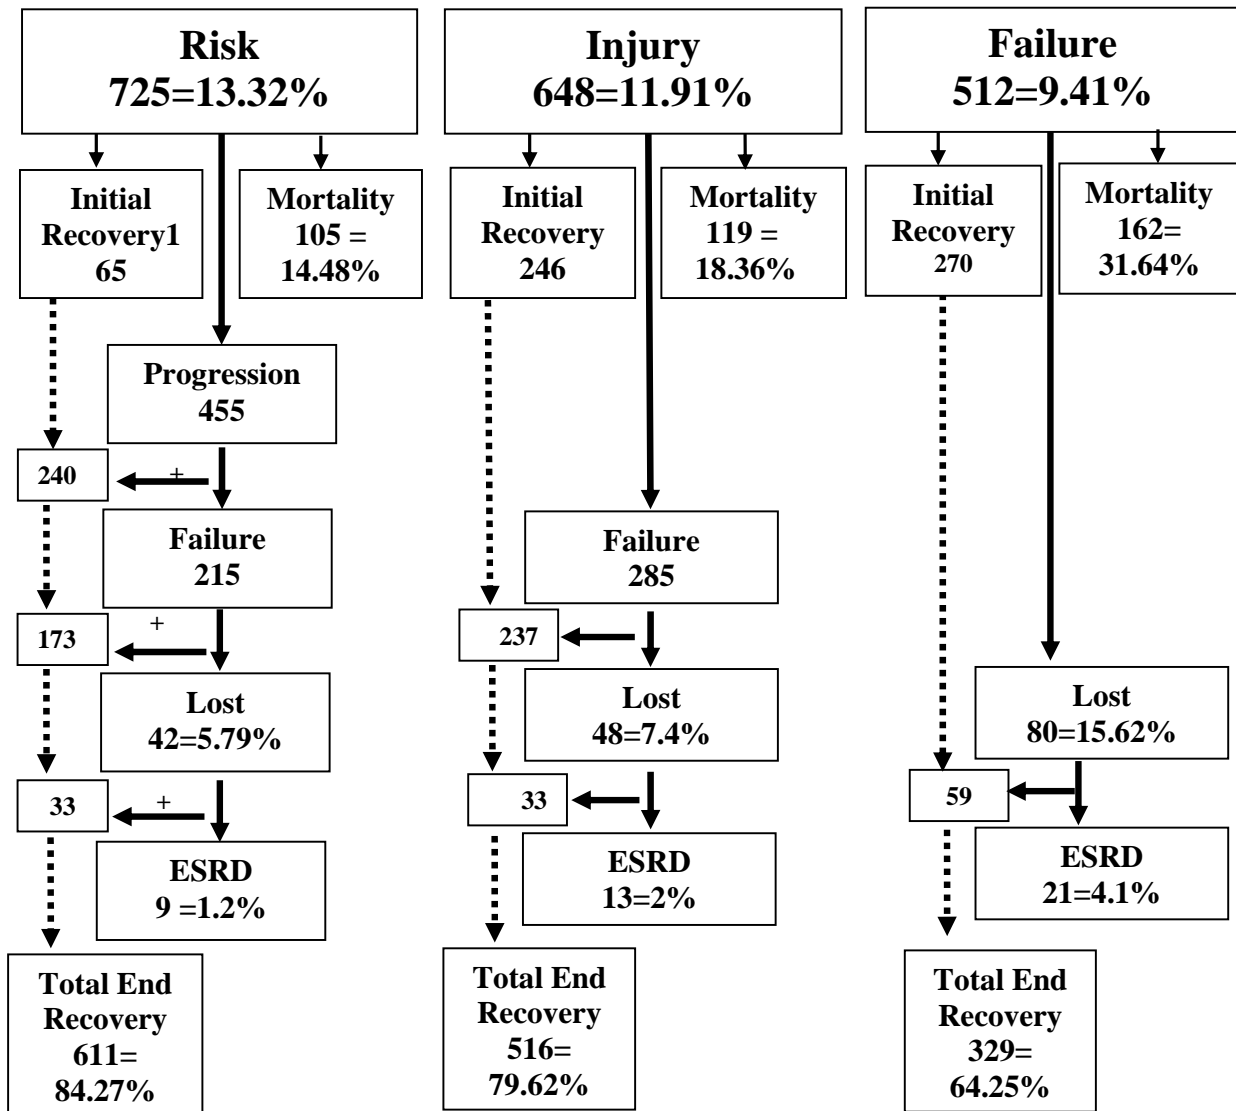

Figure (1) Natural history and Clinical outcomes stratified by RIFLE category

P value	P<0.05		P<0.05		P<0.05	

In all RIFLE classes mortality statistically significantly higher in AKI patients with other co morbid diseases versus those with AKI alone <0.05

4. Discussion

AKI previously termed ARF refers to a sudden decline in kidney function causing disturbances in fluid, electrolyte, and acid– base balance. More than 35 definitions of AKI currently exist [4].The Acute Dialysis Quality Initiative convened in 2002 and proposed the RIFLE classification, specifically for AKI in critically ill patients [3].AKI in the ICU is

common, increasing in incidence [27] and is associated with a substantial increase in morbidity and mortality [28].There is limited information on whether the epidemiology of AKI in critically ill patients in different regions of the world has changed over time and there is controversy on whether its outcome has improved [29]. So we sought to estimate the prevalence of AKI in ICU and assess the ability

of the RIFLE criteria to predict the outcome in ICU patients.

The prevalence of AKI in the internal medicine ICU, Zagazig University Hospital was 34.65%, classified by RIFLE criteria into Risk, Injury and Failure. 13.32%, 11.91%, and 9.41% respectively. Nearly similar results obtained by Bagshaw *et al.*, [30] who reported that AKI occurred in 36.1% of ICU patients and classified by RIFLE criteria R, I and F 16.2%, 13.6% and 6.3% respectively. Their study was done in 57 ICUs across Australia during a 5 year period and this may explain the slight difference in comparison to the current study. Also Ostermann *et al.*, [9] study reported the prevalence of AKI in 41,972 ICU patients was 35.8% and classified by RIFLE criteria R, I and F. 17.2%, 11 % and 7.6 %, respectively.

In contrary to our results Thakar *et al.*, [31] study found that the overall prevalence of AKI among patients admitted to Veterans Affairs ICUs including 71,486 patients the prevalence of AKI was 22%, however this difference can be explained by the fact that they studied patients who complicated by AKI during their stay in the intensive care unit. The lowest prevalence of the AKI in ICU reported by Brevet *et al.*, [23] was 7%, their study focused on the AKI occurring in the ICU in a 20 center, prospective 6 months performed in France in 1991, but this old study was carried for a short period and did not depend on RIFLE criteria for diagnosis of AKI. This low prevalence may explore the higher sensitivity of the RIFLE criteria for diagnosis of AKI and suggesting that the incidence of detectable AKI is annually increasing and much higher than previously appreciated.

The highest prevalence was reported by Hoste *et al.*, [28] was 67% ,with RIFLE classes R, I and F 28%, 27% and 12% respectively, they constructed a retrospective cohort study in seven ICUs serving medical, surgical, neurological, trauma and solid organ transplant patients during a 12 month period, this can be explained by the fact that their study was carried on different ICUs including surgical, neurological, trauma and solid organ transplant patients, expected to include high risk patients after surgery, trauma, hence they are more prone to AKI.

Regarding the progression of AKI to the next stages, the present study found that 62.75% of patients with RIFLE class R progressed to class I or class F, and more than 43.98% of the patients with RIFLE class I progressed to class F, this was compatible with the result obtained by Eric *et al.*, [32] study which found that more than 50% of patients with class R progressed to class I or class F, and more than one-third of the patients with class I progressed to class F.

The percentage of patients who lost kidney function and required RRT in this study were 9%, those patients when stratified by RIFLE criteria their percentages increase with worsening RIFLE classes 5.79%, 7.4% and 15.62, respectively. Nearly similar results obtained by Eric *et al.*, [32] who found in their study patients requiring RRT classified by RIFLE criteria Risk, and Failure was 4.15% and 14.2% respectively. Also Shigehiko *et al.*, [33] who found among patients who survived to hospital discharge that 13.8% required RRT at the time of discharge. The small difference in results may relate to the argumentation in timing of initiation of RRT.

The percentage of patients who developed ESRD in this study was 2.4%; we also found when those patients stratified by RIFLE criteria their percentage increase with worsening RIFLE classes. R, I and F 1.2% , 2% and 4.1% respectively, although there is limited information about the percentage of patients ended by ESRD after AKI in ICU. However the similar results were obtained by Ostermann *et al.*, [9] study which found that 2.3% patients with AKI in ICU had developed ESRD.

Regarding mortality we found that the crude mortality of AKI patients in the ICU was 20.47%. Nearly similar results were obtained by Garzotto *et al.*, [34], who found that AKI mortality in the ICU was 21.7%. We also found that the hospital mortality AKI patients stratified by RIFLE criteria increased with worsening RIFLE classes 14.48%, 18.36% and 31.64% respectively. Similar results were obtained by Bagshaw *et al.*, [30] who found progressive increased in mortality from R, I to F 17.9%, 27.7% and 33.2% respectively, Eric *et al.*, [32] found progressive increased in mortality from R, I to F 8.8%, 11.4% and 26.3% respectively also many others studies confirmed our results as Hoste *et al.*, [15], Garzotto *et al.*, [34], Kuitunen *et al.*, [35], Ahlstrom *et al.*, [36], Uchino *et al.*, [37], Ricci *et al.*, [38], Ostermann *et al.*, [9] and Abosaif *et al.*, [39].

When we compared mortality among patients with AKI versus patients without AKI, we found that mortality in patients with AKI nearly 3 folds higher than patients without AKI 20.47% versus 7.76% respectively. Similar results obtained by many studies, Bagshaw *et al.*, [40] who found 24.2% versus 8.9% respectively and Eric *et al.* [32] found ICU mortality rate stratified by RIFLE criteria R, I and F was 8.8%, 11.4% and 26.3%, respectively versus 5.5% for patients without AKI, also de Mendonça *et al.*, [41] found ICU mortality was 3 times higher in AKI patients than in other patients. Lastly Ricci *et al.*, [38] found among the 13 studies in which patient level data on mortality were available for patients without AKI; mortality was 6.9% in non-AKI patients versus 31.2% in AKI patients.

As an expecting we found that AKI patients with other co morbid diseases have worst mortality 40.69 % versus 11.6% for patients with AKI alone. Mortality also progressively increased with worsening RIFLE criteria R, I and F 30.47%, 33.55% and 60% respectively. Similar results obtained by de Mendonça *et al.*, [41] and Sirvent *et al.*, [42].

Interestingly when we compared the outcome among patients defined by SCr criteria versus those defined by UOP criteria, we found that UOP criteria carried a less mortality than SCr criteria, this mean that the UOP criteria had better predictive values than SCr criteria. These results matched with the results obtained by Eric *et al.*, [32] who reported that patients with class F based on SCr have a higher hospital mortality compared with patients having class F on UOP criteria. This result may be explained by the fact that SCr is not an early sensitive marker for AKI [1] and an early change in UOP may alarm for an early renal disease evoking early intervention. In contrary to our result Bagshaw *et al.*, [40] reported that mortality rates were higher in AKI patients defined by UOP criteria than in patients defined by SCr criteria but the modified UOP criteria used in that study may be responsible for this difference. As they defined AKI as an acute SCr level $\geq 133 \mu\text{mol/l}$ or a 24-hour UOP $< 410 \text{ ml}$ and not having received prior renal replacement therapy, these criteria different from the RIFLE criteria.

Conclusion

The prevalence of AKI in the Internal Medicine Zagazig University Hospital ICU is 34.65%. RIFLE criteria represent a simple and easy to use for the detection and classification of AKI on ICU admission and useful in predicting the outcome of AKI patients.

Acknowledgment:

The authors thank Prof. Dr. Mohammed Zanaty, Prof. Dr. Usama Khalil and Prof. Dr. Mohammed Sakr for their invaluable suggestions. Also we thank all members of Zagazig University Hospital ICU.

Abstract: This study was conducted to determine the postural changes during normal pregnancy. Forty normal primigravid women at first trimester of pregnancy (12 weeks' gestation) from the Out-Patient Clinic of Obstetric Department at Bab EL-Sheria Hospital, AL-Azhar University shared in this study. Their ages ranged from 20 to 30 years old and body mass index did not exceed 30 kg/m². Thoracic kyphosis angle, lumbar lordosis angle and pelvic inclination angle were evaluated by the formetric II at 12, 22 and 32 weeks' gestation in Spinal Shape Analysis Laboratory at Faculty of Physical Therapy, Cairo University. The obtained results showed a statistically highly significant increase ($P < 0.001$) in the thoracic kyphosis angle, lumbar lordosis angle and pelvic inclination angle between 12&22, 22&32 and 12&32 weeks' gestation. Accordingly, it could be concluded that there is a statistically highly significant increase in the thoracic kyphosis angle, lumbar lordosis angle and pelvic inclination angle during normal pregnancy.

[Amal M. Yousef, Hala M. Hanfy, Fayiz F. Elshamy, Mohammed A. Awad and Ibrahim M. Kandil. Postural Changes during Normal Pregnancy. Journal of American Science 2011; 7(6):1013-1018]. (ISSN: 1545-1003). <http://www.americanscience.org>.

Key words: Pregnancy, Posture, Formetric II, Thoracic kyphosis, Lumbar lordosis, Pelvic inclination.

1. Introduction:

Pregnancy is a normal physiologic state that is characterized by growth of both the mother and fetus. There are extensive biomechanical, physiological and structural changes to provide a suitable environment for nutrition, growth and development of the fetus as well as to prepare the mother for the process of parturition (Artal *et al.*, 2000).

Many of the dramatic changes that occur during pregnancy are mediated by the changing hormone levels. Progesterone and estrogen are well known hormones for causing salt and water retention, also relaxin secreted by the corpus luteum till the 12th weeks' gestation, then from placenta after that, tends to soften the ligaments, thus joints are more vulnerable to injuries (Peggy, 2001).

Progesterone, relaxin and estrogen hormones in pregnancy are known to affect the musculoskeletal system for the preparation of labour. Although, the effect of relaxin is disputed, but progesterone and estrogen are known to influence the biomechanical structures of the pregnant posture by changing the structure of connective tissue and increase mobility of joint capsules and spinal segment, as well as the pelvic joint structure (Schauberger *et al.*, 1996).

Deviation from good balanced posture usually results in poor posture during pregnancy, the C.O.G. is being anteriorly, the head elevated, the cervical spine hyperextended and the knee as well as ankle joints extended (Rungee, 1993).

Artal and Toole (2003) reported that increased ligamentous laxity secondary to the influence of

increased levels of estrogen and relaxin predispose pregnant women to increased incidence of strains and sprains. Also, the pregnant uterus enlarges and the mother's weight distribution is altered so, the front of the abdomen becomes heavier, and normal curvature of the lumbar spine is exaggerated. This alters the mother's gait, making falls more likely than in the non-pregnant state (Cunningham *et al.*, 1997).

Pregnant women typically develop hyperlordotic posture, which contributes to a very high prevalence (50%) of low back pain (Artal and Toole, 2003). Also, joint laxity is coupled with the increased lumbar lordosis and protuberant abdomen, which leading to unsteadiness of gait and trauma from falls as a result of loss of balance which is common during pregnancy than any other time in women's life (Gabbe *et al.*, 1996).

Postural changes have often been implicated as a major cause of back pain in pregnant women (Lane, 2007). While, Franklin and Conner-kerr (1998) found that from the first to the third trimesters of pregnancy, lumbar lordosis, posterior head position and pelvic tilt increases. However, the magnitudes and the changes of these posture variables are not related to back pain.

The increased weight in pregnancy may significantly increase the forces across joints such as hips and knees as much as 100% during weight bearing activity. Such large forces may cause discomfort to these normal joints and increase damage to arthritic or previously unstable joints (Artal and Toole, 2003).

The increasing weight is distributed primarily in the abdominal girth. After 12 weeks of pregnancy, the uterus expands out of the pelvis and moves superiorly, anteriorly and laterally. So, many of the problems evoked are postural, caused by inability of the woman to adapt to her forward movement of C.O.G that resulted in increasing the lumbar lordosis and anterior tilting of the pelvis (Mayo Clinic Staff, 2007).

Black and Anastasi, (1995) found that in 34 pregnant women lumbar lordosis and thoracic kyphosis increased between the fourth and ninth months of pregnancy. The increased lordosis could be due to increase growth and weight of the anteriorly displaced fetus, producing anterior tilting of the pelvis (Franklin and Conner-kerr, 1998). In contrast, Ostgaard *et al.*(1993) found no change in lumbar lordosis with advancing pregnancy.

Collition (1996) reported that posture changes which occur during pregnancy, help the woman to maintain balance in upright position as fetus grows.

Moreover, hyperlordotic posture causes paraspinal muscles to become shortened and strained, thus resulting in mechanical imbalance between abdominal and paraspinal muscles which contributes to a very high prevalence (50%) of low back pain in pregnant women (Fast *et al.*, 1990). Balance may be affected by changes in the posture of pregnant women, predisposing to loss of balance and increased the risk of falling (Artal & Toole, 2003).

Because of the importance of postural changes during pregnancy and their impact on the women's life during pregnancy and after delivery, so it seems to be important to study these postural changes.

2. Subjects, Material and Methods:

Subject's Criteria: -

Forty normal primigravid women having single fetus at first trimester of pregnancy (12 weeks' gestation which confirmed by ultrasound) from the Out-Patient Clinic of Obstetric Department at Bab EL-Sheria Hospital, AL-Azhar University shared in this study. Their ages ranged from 20 to 30 years old and body mass index did not exceed 30 kg/m². All participated women were housewives and free from any musculoskeletal and/or neurological disorders, previous fractures and/or operations at the back, pelvis and lower extremities, diabetes mellitus, varicose veins and hypertension. All pregnant women did not take any medications that might affect the neuromuscular functions at least three months before pregnancy and/or during the study course. Gestational age of each pregnant woman participated in this study was detected and calculated starting from the first day of last menstrual cycle – date of inclusion in the study then ÷ 7 days and confirmed by

ultrasonography before the beginning of this study by obstetrician.

Instrumentation:

- 1) Recording data sheet: All data and information of each pregnant woman of who participated in this study were recorded in a recording data sheet.
- 2) Weight-height scale: It was used for measuring the body weight and height of each pregnant woman in this study to calculate the body mass index.
- 3) Ultrasound machine: It was used at start of 12, 22 and 32 weeks gestation to estimate the gestational age of the fetus and to exclude any fetal congenital anomalies, hydramnios as well as twins of each pregnant woman who participated in this study.
- 4) Formetric II: It is an optical 3D-spine, posture and measurement system, which is reliable, valid and safe to be used during pregnancy (Drerup and Hierholzer, 1994). Formetric II instrument system serves for the determination of the geometry of the back surface of the human being based on non-contrast 3D - scan and derived from it, a spatial reconstruction of the spine by means of a specific mathematical model (Drerup and Hierholzer, 1996). It was used for evaluation of all pregnant women (Fig. 1).

Fig. (1): Components of the formetric II instrument.

Methods:-

A full history was taken from each pregnant woman before starting this study at her first trimester (12 weeks' gestation) according to the items of the recording data sheet. The height was measured before starting the study, while the weight was repeatedly measured and body mass index was calculated according to the following equation: Body mass index = weight/height (kg/mr²) before starting each measurement at 12, 22 and 32 weeks' gestation. After that, each pregnant woman was instructed carefully about the evaluative procedures and she was advised to evacuate her bladder and removed her shoes as

well as socks (i.e. bare feet) before starting the measurement procedures.

Measurement Procedures:-

1- System calibration:

Formetric II has no external calibration, but it has internal calibration. That means it calibrates itself after entering the patient's personal data (internal calibration for system configuration only).

2- Data of each pregnant woman:

Before starting spinal measurement, the Physical Therapist should feed the computer with data of each assessed pregnant woman including body weight (kg) and height (cm) which are important in calibration of the measurements and should be saved in the software of the system.

3- Imaging using Formetric II:

Each pregnant woman was standing bare feet in a neutral, upright position in a distance of 2 m in front of the 3D scanning equipment. The scanner adjusted according to the height of each pregnant woman. The scanning time was very short (40ms), in order to eliminate movement artifacts. The formetric II system analyzed the backs surface form in a sophisticated, automatic way, with no need for manual fixation of markers on the vertebrae. Anatomical landmarks, vertebral position and rotation were automatically detected, using the reconstructed high- resolution surface and anatomical and pathological knowledge models. The resulting model showed the complete form and the measurement data of the examined spine and pelvis but the subject's trunk had to be bared skin (Fig. 2).

4-Processing and editing:

The data of each pregnant woman was preceded and edited into the formetric II software in which spinal image was generated.

Fig. (2): The scanning of the spine. (Posterior view)

Statistical analysis:

The collected data in this study was statistically analyzed using descriptive statistics as mean, standard deviation and percentage. Comparison of means: by using T-test and Anova test were used for comparison within groups and in between groups. Level of significance: For all the statistical tests done, the threshold of significance was fixed at the 5% level (P- value). A P-value > 0.05 indicates non significant result. A P-value < 0.05 indicates significant result and the P-value was the degree of significance. The smaller the P- value obtained, the more significant was the result (Bendate and Piersol, 1991).

3. Results:

I- Physical characteristics of the women:

The ages of the pregnant women ranged from 20 to 30 yrs, with a mean value of 25.65 ± 2.85 yrs, height ranged from 153 to 171 cms, with a mean value of 161.5 ± 0.06 cms and their weight in the 12, 22 and 32 weeks' gestation of normal pregnancy ranged from 59 to 79 kgs, 64 to 85 kgs and 69 to 93 kgs, respectively, with a mean value of 68.05 ± 7.3 kgs, 74.5 ± 7.4 kgs and 79.75 ± 7.52 kgs, respectively.

II- Thoracic kyphosis angle:

The thoracic kyphosis angle of the pregnant women at the 12, 22 and 32 weeks' gestation of normal pregnancy ranged from 44.4° to 56.4° , 50.2° to 62.7° and 57.3° to 68.4° respectively, with a mean value of $50.78^\circ \pm 3.58^\circ$, $56.86^\circ \pm 3.72^\circ$ and $63.08^\circ \pm 3.7^\circ$ respectively. There was a statistically highly significant increase ($P < 0.001$) between 12&22 weeks' gestation, 22&32 weeks' gestation and 12&32 weeks' gestation as shown in table (1), Fig. (3). Repeated measurement ANOVA revealed a statistically highly significant difference ($P < 0.001$) within subjects and between subjects.

III- The lumbar lordosis angle:

The lumbar lordosis angle of the pregnant women at the 12, 22 and 32 weeks' gestation of normal pregnancy ranged from 24.6° to 35.8° , 29° to 42.1° and 33.3° to 52.3° respectively, with a mean value of $30.55^\circ \pm 3.27^\circ$, $35.94^\circ \pm 3.66^\circ$ and $42.92^\circ \pm 5.02^\circ$ respectively. There was a statistically highly significant increase ($P < 0.001$) between 12&22 weeks' gestation, 22&32 weeks' gestation and 12&32 weeks' gestation as shown in table (1), Fig. (3). Repeated measurement ANOVA revealed a statistically highly significant difference ($P < 0.001$) within subjects and between subjects.

IV- The pelvic inclination angle:

The pelvic inclination angle of the pregnant women at the 12, 22 and 32 weeks' gestation of normal pregnancy ranged from 13.7° to 23.2°, 16.3° to 29.5° and 18.3° to 33.5° respectively, with a mean value of 18.66±3.08°, 22.78±3.53° and 27.77±3.78° respectively. There was a statistically

highly significant increase ($P < 0.001$) between 12&22 weeks' gestation, 22&32 weeks' gestation and 12&32 weeks' gestation as shown in table (1), Fig. (3). Repeated measurement ANOVA revealed a statistically highly significant difference ($P < 0.001$) within subjects and between subjects.

Table (1): Thoracic kyphosis, lumbar lordosis and pelvic inclination angles at 12, 22 and 32 weeks' gestation.

	Thoracic kyphosis angle (°)			Lumbar lordosis angle (°)			Pelvic inclination angle (°)		
	12 WGs vs. 22	22 WGs vs. 32	12 WGs vs. 32	12 WGs vs. 22	22 WGs vs. 32	12 WGs vs. 32	12 WGs vs. 22	22 WGs vs. 32	12 WGs vs. 32
Mean difference	6.01	6.22	12.33	5.39	6.97	12.37	4.12	4.98	9.11
Percentage of change	12%	12%	24%	18%	23%	41%	22%	27%	49%
t-value	18,71	19,17	37,89	6,93	8,97	15,89	8,99	10,86	19,85
Level of significance	$P < 0.001$	$P < 0.001$	$P < 0.001$	$P < 0.001$	$P < 0.001$	$P < 0.001$	$P < 0.001$	$P < 0.001$	$P < 0.001$

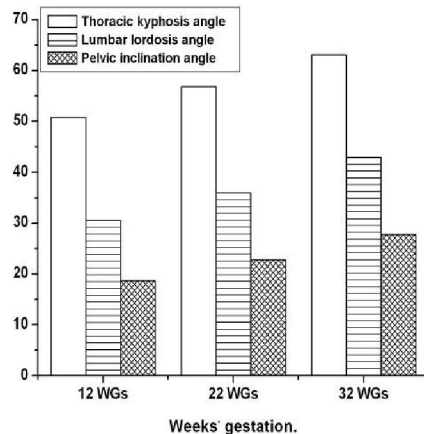

Fig. (3): Mean values of Thoracic kyphosis, Lumbar lordosis and pelvic inclination angles at 12, 22 and 32 weeks' gestation.

4. Discussion

Postural changes occurring in pregnancy may influence the musculoskeletal system and locomotor function. In the non pregnant women the line of gravity falls in line with the ear, shoulder joint, hip joint, middle of the knee joint and through the middle of the forefoot. In the pregnant woman the line of gravity falls posterior, to compensate the increase in abdominal weight (Alane, 2004).

Forty normal primigravidae women at first trimester of pregnancy (12 weeks' gestation which confirmed by ultrasound) shared in this study. In this study we studied the postural changes during normal pregnancy including lumbar lordosis angle, thoracic kyphosis angle and pelvic inclination using an

objective method (Formetric II) which gives a numerical and quantitative data.

Formetric II is an optical 3D-spine, posture and measurement system, which is reliable, valid and safe to be used during pregnancy (Drerup and Hierholzer, 1994). Formetric II instrument system serves for the determination of the geometry of the back surface of the human being based on non-contrast 3D- scan and derived from it, a spatial reconstruction of the spine by means of a specific mathematical model (Drerup and Hierholzer, 1996).

The results of this study found that, there was a statistically highly significant increase ($P < 0.001$) in the thoracic kyphosis angle, lumbar lordosis angle and pelvic inclination angle between 12&22 weeks' gestation, 22&32 weeks' gestation and 12&32 weeks' gestation.

Results of this study agreed with those of Black and Anastasi (1995) who found that lumbar lordosis and thoracic kyphosis increased between the fourth and ninth months of pregnancy.

The results of this study also, agreed with that of Ibrahim (2002) who found that, lumbar curvature showed a very highly significant increase between 20 and 24, 28 & 32 weeks' gestation, with mean values of 34.04±6.62, 43.94±7.69, 47.12±7.48 and 52.62±7.16 degrees respectively using flexible curve rule.

Also, the results of this study were supported by Franklin and Conner-kerr(1998) who found that from the first to the third trimesters of pregnancy, lumbar lordosis, posterior head position, lumbar angle and pelvic tilt increases. However, the magnitudes and the changes of these posture variables are not related to back pain.

The results of the current study supported by those Bullock *et al.* (1987) who found a significant

increase in lumbar and thoracic curves during pregnancy, which was still evident at the end of puerperium.

The increase in the thoracic kyphosis angle, lumbar lordosis angle and pelvic inclination angle during pregnancy could be explained by the changing hormone levels. Progesterone and estrogen are well known hormones for causing salt and water retention, also relaxin secreted by the corpus luteum till the 12th weeks gestation, then from placenta after that, tends to softens the ligaments, thus joints are more vulnerable to injuries (Peggy, 2001).

Progesterone, relaxin and estrogen hormones in pregnancy are known to affect the musculoskeletal system for the preparation of labour. Although, the effect of relaxin is disputed, but progesterone and estrogen are known to influence the biomechanical structures of the pregnant's posture by changing the structure of connective tissue and increase mobility of joint capsules and spinal segment, as well as the pelvic joint structure (Schauberger *et al.*, 1996).

The increased lordosis adaptation could be due to increase growth and weight of the anteriorly displaced fetus producing anterior tilting of the pelvis (Black and Anastasi, 1995).

The body's C.O.G. shifts upward and forward due to the increases in weight of the uterus and its contents, lumbar lordosis increase to compensate for the shift of the C.O.G. and the knees hyperextended probably due to the change in the line of gravity, weight shifts toward the heels to bring the C.O.G. to a more posterior position (Kisner and Colby, 1990).

The increasing weight is distributed primarily in the abdominal girth. After 12 weeks of pregnancy, the uterus expands out of the pelvis and moves superiorly, anteriorly and laterally. So, many of the problems evoked are postural, caused by inability of the woman to adapt to her forward movement of C.O.G that resulted in increasing the lumbar lordosis and anterior tilting of the pelvis (Mayo Clinic Staff, 2007).

This increase could be explained as pelvic tilt is controlled by muscular action of the abdominal muscles, hip flexors, hip extensors and spinal extensors muscles. The alternation of strength or resting length of these muscles will also change the angle of pelvic tilt and, in turn, the lumbar curvature. Increased lordosis will result from a forward tilt of the pelvis occurring due to weak abdominal muscles, the lordotic posture is one in which the lumbosacral angle is increased and the pelvis tilts forward. The condition may exist in parallel with increased thoracic kyphosis and a forward-held head. The anterior longitudinal ligament will be lengthened, the posterior lumbar disc space narrowed, and the facet joint approximated with accompanying dural

compression and synovial irritation. Hip flexors are tight, as well as lumbar extensors, while the abdominals are weak and stretched (Franklin and Conner-kerr, 1998).

The results of this study are not in agreement with the results of Ostgaard *et al.* (1993) who found that no change in lumbar lordosis with advancing pregnancy.

Conclusion:

It can be concluded that there was a statistically highly significant increase in the thoracic kyphosis angle, lumbar lordosis angle and pelvic inclination angle during normal pregnancy.

Predictors of Fertility among Egyptian Females at Reproductive Age at El-Manial Maternity Hospital

Hanan Fahmy Azzam*

Lecturer of Maternal & Newborn Health Nursing, Faculty of Nursing, Cairo University

*Hananha_azzamaz@yahoo.com

Abstract: Background: The most common and well documented risk factors which can contribute to female infertility include over weight or underweight; hormonal imbalances; fibroid; reduced oocyte quality; chromosomal abnormalities; sexually transmitted diseases; age older than 27; history of pelvic inflammatory diseases; smoking and alcohol intake; and immune system disorders. **Aim** of this study was to explore the predictors that might affect Egyptian female fertility. **Subject & Methods. Design:** A Descriptive design was adopted in this study to explore the predictors that might affect Egyptian female fertility. **Sample,** a total of 300 married infertile women were recruited from the outpatient gynecological clinic at El Manial Maternity Hospital, Cairo University, Egypt according to the certain criteria. **Tools** utilized for Data collection were collected by using an interviewing questionnaire schedule. **Results of the present study** revealed that age of the woman (P=0.008); age at marriage (P=0.007); BMI (P=0.010); eat snacks (P=0.043); fatty saturated diet (P=0.029); polycystic ovary (P=0.040); cervicitis (P=0.012); utilized contraceptives methods (P<0.001); frequency of sexual intercourse/week (P=0.028) were a predictors that might affect the female fertility. **The study concluded that,** the women with the following profile: older age at marriage, overweight and obese, depending on fatty saturated diet, eat snacks, had history of polycystic ovarian syndromes, had cervicitis, used contraceptive methods, might be at risk for the occurrence of infertility. **Recommendation,** based on the findings of the present research the following recommendation is suggested: Raise women's awareness regarding to adopting healthy life style as follow dietary program and practice exercising.

Key words: Predictors - Fertility –Reproductive Age

1. Introduction

Infertility is a widespread problem that has an emotional, psychological, social and economic impact on couples and society (Ricci, 2009). Infertility is a medical diagnosis of the reproductive system, and is defined as the inability to achieve pregnancy after one year of frequent, unprotected intercourse (Orshan, 2008). Primary infertility applies to a man or woman who has never been able to conceive while, secondary infertility applies to an inability to conceive after one or both partners have conceived previously (Ricci, 2009). Women older than 35 years having difficulty conceiving may receive a diagnosis of infertility before a full 12 months. (Covington and Burns, 2006).

Worldwide, the prevalence of infertility is approximately 13%, with the range from 7-28%, depending on the age of the woman (kumar Ashim et al., 2007). In Egypt, El-awady and Abdelazeem (2008) reported that the prevalence of the primary and secondary infertility was 2.5% and 7.9% respectively; also, they added that, the overall prevalence of infertility is 10.4%. In normal fertile couples having frequent, timing intercourse, the success of conception is estimated to be approximately 20-25% (Kelly-Weeder & Cox, 2006).

Approximately 90% of couples with unprotected intercourse will conceive within one year (Fraser & Cooper, 2010).

Ricci (2009) mentioned that, the risk factors which can contribute to female infertility include over weight or under weight (can disrupt hormone function); hormonal imbalances leading to irregular ovulation; fibroid; tubal blockages; reduced oocyte quality; chromosomal abnormalities; sexually transmitted diseases (STDs); age older than 27; history of Pelvic inflammatory disease (PID); smoking and alcohol intake; decreased frequency of coitus; congenital anomalies of the cervix and uterus; and immune system disorders.

Rowe (2006) reported that, as a woman ages beyond 35years (particularly after age 40years), the likelihood of becoming pregnant is less than 10% per month, and a woman's peak fertility is in her early 20s. In addition, Gurevich (2010) indicated that, healthy couples younger than 30 years who have regular sexual intercourse and use no contraception have a 25% to 30% chance of achieving pregnancy each month.

Worldwide, PID is one of the leading causes of ectopic pregnancy and preventable infertility which affect women's upper reproductive tract,

including the structures of the uterus, ovaries, and fallopian tubes (salpingitis) which is considered the most common manifestation of the disease (Bosky, 2007). Moreover, PID is known to be a long-term consequence of sexually transmitted diseases as well as of bacterial vaginosis, pelvic surgery, and other gynecologic procedures that cross the cervix (Morse, 2010). In the same context, women who are not treated for PID right away can experience serious complications, ranging from infertility to ectopic pregnancy to chronic pelvic pain (Mardh, 2004).

Many lifestyle choices can negatively affect female fertility. Women who smoke are three times likelier to have difficulty conceiving and less likely to become pregnant with infertility treatment and the more cigarettes a woman smokes the less her chances of conceiving (Zavos & Panayiotis, 2011). Also, they added that, women smokers who do become pregnant have more miscarriages. Moreover, Zosia (2011) reported that tobacco smoke can reduce female fertility by affecting hormonal function within the ovary which can reduce the number and quality of eggs; and ultimately could impair fertilization.

Obesity has a strong association with infertility and menstrual irregularities, while, some of the ovulation problems and menstrual changes are explainable by women with polycystic ovarian syndrome (PCOs) who are also obese, and women who do not have PCOs but are overweight also have the same problems (sallmen,2006). In addition, Hoeger, (2006) found that obesity at 23 years and at 7 years both independently increased the risk of menstrual problems by the age 33 years. In the same context, Garcia, (2006) reported that overweight and obesity in early adulthood may increase the risk of menstrual problems and infertility. Also, added that 20% over ideal weight is considered obese, and a body mass index (BMI) of 25-30kg/m² is considered overweight and a BMI of over30 is considered obese.

Ovulatory disorders are the leading cause of female infertility, resulting in the disruption of hormones, menstrual cycles, and conception; and approximately 15% of such disorders are linked to weight disorders, mainly being overweight and obese (Hirschberg, 2009). Also, added that women who are overweight and obese are less likely to respond to fertility drugs, because excess weight interferes with the proper absorption of a variety of drugs used in infertility treatment.

Moreover, abnormal hormones can be addressed as a result of excess weight which can negatively impact on ovulation and cause over-production of insulin, which may cause irregular ovulation (Boyles, 2007). Also, there is a link between obesity, excess insulin production and the infertility condition known as polycystic ovarian

syndrome which associated with irregular menstrual cycles, anovulation (decreased or stopped ovulation), obesity and elevated levels of male hormones (Pasquali & Gambineri, 2006).

Cottrell (2010) reported that, frequent vaginal douching is associated with adverse reproductive health outcomes as increased the risk of pelvic inflammatory disease, secondary infertility, and ectopic pregnancy. Also, added that douching may impact on health because it disturbs the chemical and microbial balance of the vagina and possibly leading to bacterial vaginosis and other bacterial infections. Moreover, douching may force pathogens up through the cervix causing uterine infections where organisms are more likely to cause pelvic inflammatory disease, an infection linked with infertility (Boskey, 2007).

The nurse has a crucial role in the prevention and management of infertility, the nurse should perform careful assessment for the presence of risk factors as age, chronic disease, stress, and poor diet. Also, education is another important role, that the nurse should teach the couples the signs and timing of ovulation, the most effective times for intercourse, other fertility awareness behaviors that the nurse may inform the women about avoiding douches and avoiding artificial lubricant. Moreover,, the nurse may teach the women about home assessment of cervical mucus and basal body temperature (BBT) recording. The nurse can alleviate some of the anxiety associated with diagnostic testing by offering explanation about timing and reasons for each test. In addition, the nurse should be familiar with the fertility problem, the couple's stage of coping, and fertility centers for referral (Ricci, 2007 and Davidson, London and Ladewing, 2006).

Significant

Infertility has a profound emotional, psychological and economic impact on affected couples and society (Davidson, London and Ladewing, 2006). According to statistics collected by the Centers for Disease Control (2011) reported that 6.1 million women between the ages of 15 to 44 years have an impaired ability to have children, and 2.1 million married couples are experiencing infertility, also, statistics found that 9.2 million women had made use of infertility services at some time in their life. However, in Egypt there is scattered nursing researches that determine factors affecting female fertility; so, the current study will explore the profile of infertile women and determine the factors affecting female fertility. Also, this study will contribute to improve the nursing practice especially in relation to women follow – up and monitor for

early detection of problems that may predispose to infertility.

Operational Definition

Predictors: in the current research refers to factors that might affect female fertility as measured by interviewing questionnaire schedule.

Aim

The aim of this study was to explore the predictors that might affect Egyptian female fertility.

Research Question

1- What are the Predictors that might affect Egyptian females at reproductive age?

2. Subjects and Methods

Design

A Descriptive design was adopted in this study to explore the predictors that might affect Egyptian female fertility.

Setting

The setting used to carry out this research was the outpatient gynecological clinic at El Manial Maternity Hospital, Which is a university, affiliated hospital providing free health care to outpatient gynecologic patients, as well as inpatient. The total annual patient visits to outpatient infertility clinic are 2219 (statistic department, 2010) and care is provided by physicians, as well as professional and diploma nurses who are responsible for giving nursing care.

Sample

A total of 300 married infertile women were recruited for the study according to the following inclusion criteria: women having primary or secondary infertility, at the reproductive age, and can read and write. Women who had tubal factors of infertility and their husbands were responsible for infertility were excluded.

Tool

Tool used to collect data was the interviewing questionnaire schedule. It was designed and filled by the researcher and the content of tool was determined through an extensive review of literatures about infertility. This tool includes data related to **a)Socio-demographic characteristics and women lifestyles** as age, educational level, occupation, duration of marriage, weight, height, and calculation of BMI, nutritional habits as kind of diet, had snakes, and cigarettes smoking; **b)obstetrical profile** as Parity, number of abortion, mode & place of previous delivery, age at marriage, menstrual history as (age at menarche, regularity, interval,

duration and amount of menstrual flow, consistency, using of medications to regulate her menstruation, or to induce ovulation, and menstrual abnormalities); **c) medical history** includes chronic disease as anemia, diabetes, heart disease, renal disease, liver disease, thyroid problems, and toxoplasmosis; **d) gynecological and sexual history** as ,pelvic inflammatory disease, vaginitis, cervicitis, polycystic ovarian syndrome, and types & duration of contraceptive methods if used, frequency of intercourse/week, had dyspareunia, use of chemical lubricants for intercourse and use of antiseptic douches immediately after intercourse.

Tool Validity

Tool was submitted to a panel of three medical and nursing experts in the field of obstetrics and gynecology to test the content validity. Modification was carried out according to the panel judgment on clarity of sentences and the appropriateness of content.

Ethical Consideration

An official permission was granted from the director of the El Manial Maternity Hospital. The researcher introduced herself to the women who diagnosed with infertility and met the inclusion criteria and informed them about the purpose of this study in order to obtain their acceptance to participate in this study. The researcher assured that the study posed no risk or hazards on them. All women were informed that the participation in the study was voluntary. A written consent was obtained from women who were willing to participate in the study.

Pilot Study

A pilot study was carried out on 10% of the total sample to check clarity of items and determine the feasibility of the study.

Procedure

Data was collected through a period of 9 month from May 2010 to January 2011. Researcher collected data after the women had been fully informed and consented for participation in the study. Data was collected through interviewing questionnaire schedule.

1. Interviewing schedule to collect data related to socio-demographic characteristics and lifestyles, obstetric profile, medical history, gynecological, and sexual history. The researcher met the women at outpatient gynecological clinic where they came for the first time or for follow up of their condition. The researcher asked questions in simple Arabic language and recorded the answers in the schedule. The

interview consumed about 20 minutes for each woman.

Also, Anthropometric assessment was carried out after obtaining the baseline data, that the researcher measured women height through tape measurement. and weight utilizing bath scale, accuracy was obtained through balancing zero prior to obtaining each weight and then body mass index is calculated by dividing the subject weight in kilograms by the square of her height in meters ($BMI = \text{kg} / \text{m}^2$). World Health organization (WHO) (2000); Jeannette, Robert and Cynthia (2004) categorized the body mass index as the following values: A BMI less than 18.5 is under weight; A BMI of 18.5 – 24.9 is normal weight; A BMI of 25.0 – 29.9 is overweight; A BMI of 30.0 – 39.9 is obese; A BMI of 40.0 is higher or severely (or morbidly) obese. The Anthropometric assessment was consumed about 10 minutes for each woman.

Information about the **assessment of menstrual flow amount** was obtained through asking women to point on the picture which illustrated the amount of blood stain in peripad and recorded based on Nichols and Zwelling (1997, p998) as (peripad blood stain < 10ml = scant; peripad blood stain 10: 25 ml = Mild; peripad blood stain 25: 50ml = moderate; peripad blood stain 50:80ml = heavy). Information about the **physical and gynecological assessment** was obtained from the physician to complete data related to these parts.

Statistical analysis

Collected data were coded and tabulated using personal computer. Statistical package for social science (SPSS) version 11 was used. The researcher used the descriptive as well as inferential statistics. The descriptive statistics include the arithmetic Mean as an average, describing central tendency of observation of each variable studied; the standard deviation as a measure of dispersion of results around the mean; and the frequency distribution and percentage of observation for each variable studied were used. Multiple regression analysis was also used as inferential statistics to examine the differences and similarities within the sample and to identify predictors that might affect female fertility at reproductive age. Statistical significance was considered at p -value <0.05.

3. Results

Findings of this descriptive research will be presented in two main sections: 1) description of the sample; 2) predictors that might affect female fertility.

I: Description of the Sample

This section includes: a) socio-demographic characteristics and women lifestyles, b) infertility

description, c) obstetrical profile, d) medical history, e) gynecological and sexual history.

a) **Socio-demographic characteristics and lifestyles**, the results indicated that the age range was 16-44 years with a mean of 28.62 ± 6.32 years. Forty-nine point seven percent of the sample was distributed at the age category (21 - 30 years); while 36.3% of them was distributed at the age category (31-40 years); 4% of them was distributed at the age category (41-44 years); and 10% of them was distributed at the age (≤ 20 years). Ninety-one percent of sample was housewives. High percentages of the sample (33.7%) had secondary school education, and low percentages of the sample (10%) had primary school education, while, (27.3%, 14.7%, and 14.3% respectively) of them can read & write, had preparatory and university education.

The weight range of the sample was 38-162 kilograms, with a mean of 73.40 ± 17.00 kilograms; and the height range of the sample was 1.43-1.76 meter, with a mean of 158.1 ± 6.212 meter, regarding to BMI categories of the sample, the results revealed that 1.3% of the sample was under-weight, while, 24.4% of the sample was normal weight. However, 33.3% of the sample was overweight, while 35% of the sample was obese, and 6% of the sample was morbidly obese, with mean BMI of 29.3 ± 6.31 (table, 1). Fifty seven percent of the sample had snacks between meals, and 42.3% of them depend on fatty-saturated diet. While, 2% of the sample was cigarettes smokers with a number range of 5-20 cigarettes/ day with a mean of 10.3 ± 6.02 cigarettes.

b) **Infertility description**, 57% of the sample had primary infertility, while 43% had secondary infertility. Mean duration of infertility was 4.32 ± 3.55 years.

c) **Obstetrical profile**, Age range at marriage was 15-40 years with a mean of 25.99 ± 7.53 years. Regarding to the menstrual history, age range at menarche was 8-20 years with a mean of 12.88 ± 1.51 years; 61% of the sample had irregular menstruation; menstrual duration range was 2-15 days with a mean of 4.55 ± 1.66 days; also, women had moderate, mild, and heavy amount of menstruation (54%, 12%, & 31.7% respectively), and only 2.3% of them had scanty menstruation. Forty point seven percent of the sample had menstrual abnormalities as oligomenorrhea, menorrhagia, and hypermenorrhea (50%, 32.8%, and 17.2%, respectively). In addition, 28% of the sample used hormones to regulate their menstruation, while, 85% used it with the purpose of

induce ovulation. Regarding to parity, 43% of the sample had secondary infertility, and 17.3% of them had history of abortion, while 25.7 %of them completed their pregnancy (15.7 % primipara, and 10 % multipara).

Fifty-seven point one percent of them were delivered by cesarean section (CS), while, 28.6% of them were delivered by normal vaginal delivery (NVD), and 14.3% of them were delivered by vaginal delivery with episiotomy. Eighteen-point three percent of the sample used different methods of contraception such as intrauterine device, contraceptive pills and contraceptive injections (58.2%, 21.8%, and 20% respectively) with mean duration of contraceptive use was 19.60 ± 12.745 month.

d) Medical history, results indicated that 15.3% of the sample had history of medical disease as anemia, renal disease, rheumatic fever, hypertension, rheumatoid arthritis, diabetes mellitus, hyperthyroidism, and toxoplasmosis (45.6%, 21.7%, 10.8 %, 8.6 %, 8.6 %, 6.5 %, 6.5%, and 6.5% respectively).

e) Gynecological and Sexual history, results indicated that 79.7% of the sample had history of gynecological disease as vaginitis, polycystic ovary (PCO), cervicitis, and pelvic inflammatory disease (29 %, 36.3%, 32.2%, and 2.5% respectively). Mean sexual intercourse/week was 3.04 ± 1.46 times, 52% of the sample had sexual intercourse (3-4 times), while, 36.4% of them had sexual intercourse (<3 times); and only 10.6% of them had sexual intercourse (>4 times); 16.7% of the sample had dyspareunia; 8.7% of the sample used antiseptic douches immediately after intercourse and only 1.3% of the sample used chemical lubricants for intercourse.

II: Predictors that might affect female fertility

This section includes Predictors that might affect female fertility. Multiple regression Analysis was carried out using Socio-demographic and lifestyles predictors, obstetrical predictors, and gynecological & sexual predictors, as independent variables and female fertility as dependent variable to explore the predictors that might affect female fertility.

1. Demographic and lifestyles Predictors. Results indicated that age, BMI, fatty saturated diet and had snacks were important predictors that might affect the female fertility ($P=0.008$, 0.010 , 0.029 & 0.043 respectively); However, educational level, and cigarettes smoking were not statistically significant ($P = 0.380$, & 0.735 respectively) (figure, 1).

2. Obstetric Predictors. Results indicated that, age at marriage, use of family planning methods, menstrual irregularities, menstrual abnormalities, and mode of previous delivery were a predictors that might affect the female fertility ($P=0.007$, <0.001 , <0.001 , <0.001 & <0.001 respectively). However, age at menarche was not statistically significant ($P = 0.319$) (figure, 2).

3. Gynecological and Sexual Predictors. Polycystic ovary, cervicitis and frequency of sexual intercourse / week were a predictors that might affect the female fertility ($P= 0.040$, 0.012 & 0.028 respectively). On the other hand, history of pelvic inflammatory disease (PID), vaginitis, dyspareunia, use of chemicals lubricants for intercourse, and use of antiseptic douches immediately after intercourse were not statistically significant ($P = 0.238$, 0.772 , 0.340 , 0.678 , & 0.244 respectively) (figure, 3&4).

Table (1): Distribution of the Sample According to Category of Body Mass Index (n=300)

Body Mass Index Category	Frequency	%
A BMI < 18.5 (under weight)	4	1.3
A BMI 18.5-24.9 (normal weight)	73	24.4
A BMI 25-29.9 (over weight)	100	33.3
A BMI 30-39.9 (obese)	105	35
A BMI >40 (morbidly obese)	18	6

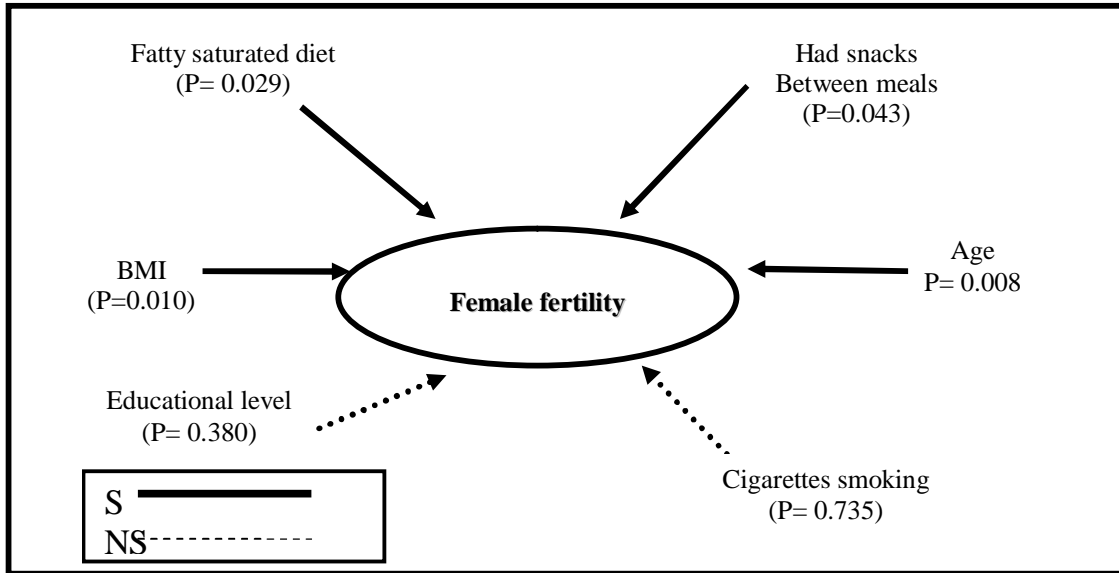

Figure (1) Socio-demographic and Lifestyle Predictors That Might Affect Female Fertility

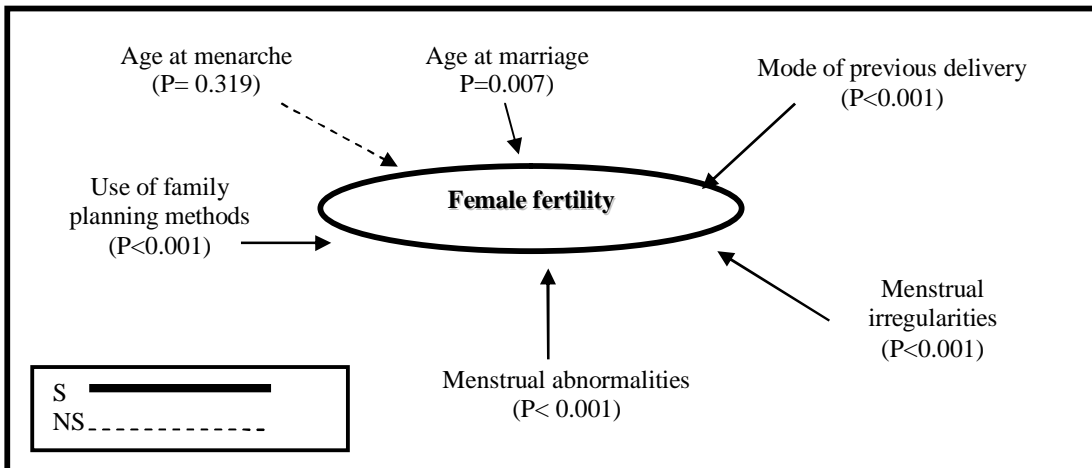

Figure (2) Obstetric Predictors That Might Affect Female Fertility

Figure (3) Gynecological Predictors That Might Affect Female Fertility

Figure (4) Sexual Predictors That Might Affect Female Fertility

Discussion

This research presents important findings related to Predictors that might affect females fertility that women may have risk factors that can contribute to infertility, and those risk factors can be genetic, environmental or related to lifestyle, and the most common and well documented risk factors for infertility in women are age, obesity, pelvic inflammatory diseases, polycystic ovarian syndrome, timing & frequency of sexual intercourse, and menstrual abnormalities. Results of this research by utilizing the Multiple regression Analysis showed that demographic characteristics and lifestyle predictors as age of the women, body mass index, fatty saturated diet, and had snakes are a predictors that might affect the female fertility, while educational level and cigarettes smoking didn't affect the female fertility. Age of the women, body mass index, and fatty saturated diet play a crucial role in declining the female fertility.

Findings of this research indicated that slightly less than half of the sample was in the age range 31-44 years old and only tenth of the sample was (≤ 20 years). This finding is matched with the data in the study of Gurevich, (2010) who reported that, as a woman ages beyond 35 years (and particularly after age 40 years), the likelihood of becoming pregnant is less than 10% per month. Moreover, this finding is supported by Rowe, (2006) who reported that fertility reach peak in most women in the 20s, and gradually begins to decline in the late 20s, and around age 35, fertility starts to decline at a much more rapid pace. This natural declining in the fertility by aging may be due to women are born with all eggs they ever have, while they are born with over a million eggs, and by puberty just 300,000 are left, from this huge number

of eggs, only 300 will ever become mature and be released in the process of ovulation. Also, way before menopause begins, women' bodies reproductive capabilities slow down, becoming less effective at producing mature, healthy eggs. As women age and become closer to menopause, their ovaries respond less well to the hormones that are responsible for helping the eggs ovulate (Gurevich, 2010).

More than two-thirds of sample was overweight and obese, slightly less than half of them depending on fatty saturated diet on their meals, and had snakes between meals and these factors have a significant relation with declining female fertility. These findings are supported by Pasquali & Gambineri (2006), who reported that obese women are characterized by comorbidities particularly type 2 diabetes mellitus and cardiovascular diseases, also, they develop some specific problems, including fertility-related disorders. Moreover, findings are matched with the data of the study of Pasquali, Gambineri & Pagotto (2006) who reported that women who extremely overweight were 43% less likely to conceive than women who were either of average weight or slightly obese. He added that weight and menstrual irregularity are related and weight loss of 15lbs (6.5kg) in anovulatory obese women results in restoring ovulation and return to fertility for many women.

In the same context, these findings are supported by (Steeg, 2007) who reported that women with BMI of 30 or more had the most trouble conceiving during their reproductive life, women with BMI of 35 was found to be 26% less likely to achieve a spontaneous pregnancy than women who were normal weight, and women with BMI of 40 or more was 43% less likely to get pregnant. In addition,

Chavarro, Rich-Edwards, Rosner and Willett (2008), found that eating disorders, constant stress, depending on carbohydrate and junk food intake had been shown to lead weight gain which had in turn linked to fertility problems. These findings may be related to that the main factor implicated in the association between obesity and fertility-related disorders is insulin excess, which accompanies insulin resistance, consequently, hyper-insulinaemia may be directly responsible for the development of androgen excess, through its effects in reducing sex hormone-binding globulin synthesis and circulating concentrations, and in stimulating ovarian androgen production rates, which in turn, represents one of the major factors leading to altered ovarian physiology and associated Ovulatory disturbances. In addition, obesity-associated hyperleptinaemia may represent an additional factor involved in anovulation, not only through the induction of insulin resistance, but also through a direct impairment of ovarian function.

Unfortunately, the findings of this research don't support that cigarette smoking to be a predictor variable that might affect female fertility and there is no clear understanding of this contradiction. However, this is may be due to the minority of the sample were smokers. This finding is contradictory with the data of the study of Deleon (2011), who reported that, women who smoke are three times likelier to have difficulty conceiving. Also, added that, tobacco smoke lead to diminished oviductal functioning in women which could impair fertilization. Also, this finding is in contrast to data from Zosia (2011) who found that, smoking can reduce female fertility by affecting hormonal function within the ovary, and also can reduce the number and quality of eggs.

Findings of this research indicated that obstetrical factors as age at marriage, menstrual irregularities, menstrual abnormalities, mode of previous delivery, and use of contraceptive methods are predictor variables that might affect female fertility while, age at menarche, didn't affect the female infertility. Age at marriage, menstrual irregularities, menstrual abnormalities, mode of previous delivery, and use of contraceptive methods play a fundamental role in declining the female fertility. Findings of this research indicated that slightly less than third of the sample married at early age and more than third of them married at old age. This finding is matched with the data in the study of Yang, Shen, Chen, and Chen (2011) who reported that, the prevalence rate of infertility was increased in the women whose marriage age were younger than 20 years or elder than 29 years old. Also, this finding is similar to the data of the study of Vahidi, & Adalan (2009) who found that, age at marriage had a negative association with decreased female fertility.

In addition, this is in agreement with Orshan,(2008) who reported that women waiting until after age 35 to have children may having trouble getting pregnant. Also, this finding is matching with study findings of Madara (2008), reported that, women who married at elder age may have a 50% decrease in their fertility rate.

Moreover, slightly less than two-thirds of the sample had menstrual irregularities and more than one-third of them had menstrual abnormalities as oligomenorrhea, menorrhagia, hypermenorrhea, and polymenorrhea. So, there is an association between menstrual irregularity, menstrual abnormalities, and the declining of female fertility which in turn reduce chances of achieving pregnancy. These findings are supported by Small (2011), who reported that, women with irregular menstruation had reduced probability of pregnancy compared with regular menstruation. Also, the findings is in agreement with the data of Sallmen, (2006) who demonstrate that, ovulation problems and menstrual irregularities are experienced by women diagnosed with polycystic ovarian syndrome, endometriosis, uterine fibroid (Hoeger, 2006). This may be due to that those previously mentioned problems may blocked fallopian tubes, disturbed the reproductive hormones which are positively linked with increased incidence of female infertility. Moreover, Boyles, (2007) who found that, endometriosis can affect fertility because the endometrium can scar and cause blockages within the ovaries or fallopian tubes, and women may have very heavy periods. Also, Pasquali, Patton, and Gambineri, (2007) reported that, about 30% to 50% of women with endometriosis are infertile, making it one of the top three causes for female infertility.

Using of contraceptive methods especially Intrauterine Devices (IUDs) is a fundamental indicator of the female infertility. Almost half among those who used contraceptive methods utilized IUD. Corcoran, (2008) reported that, the most profound complications of IUDs are infection, pelvic inflammatory diseases, and infertility. Also, added that, the serious complications due to infection associated with an IUD may prevent women from being able to become pregnant in the future. This infection may be related to that while inserting IUD into uterus it is possible that bacteria will hitch a ride on the IUD device, enter the uterus causing it to become infected and damaged which can lead to infertility. Moreover, Epstein, (2010) added that, with the progesterone-releasing IUD, 70% of women notice gradual lessening of menstrual bleeding after two years of use and 30% may notice a complete cessation of menses, this is may be due to that progesterone hormone can cause thinning of the lining of the uterus, and in some women,

pharmaceutical contraception has been shown to adversely affect or destroy the cervical fluid needed for conception, so, indicated to female infertility. In contrast, with the data of Delborge et.al.,(2002) who demonstrated that, the use of IUD doesn't affect future fertility of women wishing to become pregnant following removal of IUD.

Regarding to the Gynecological factors, Results revealed that polycystic ovarian syndrome (PCOs) and cervicitis are predictor variables that might affect the female fertility. PCOs had a strong link with female infertility. Findings of this research indicated that more than one-third of those women who had gynecological problems complained from PCOs, and more than one-third of them complained from cervicitis. This finding is in agreement with the study data of Robert & David, (2009) who reported that, polycystic syndrome is linked to women's hormonal imbalances which include symptoms like irregular periods, repeat miscarriages, male-pattern hair loss, male-type facial and body hair, acne, and obesity, and those symptoms are associated with increased incidence of infertility. In addition, up to 40% of women with PCOS have insulin resistance, and up to 10% get type 2 diabetes by the time reach age 40 and high insulin level can increase the production of male hormones and make PCOS worse and ultimately infertility (Robert & David, 2009).

Moreover, Cervicitis also, is a predictor variable that might affect the incidence of infertility type. This finding is in agreement with Grueva and Borisov (2006) who reported that, infection (cervicitis) in the cervical canal was a sensitive indicator to female infertility which in turn cause weak in the ability of the sperm motility; abnormal changes in PH which kill sperms and thicken cervical secretion plug cervical canal and affect the penetration ability of the sperm.

On the other hand, pelvic inflammatory disease (PID), and vaginitis are not predictor variables that might affect female fertility. This is may be due to that less than one-third of the sample had vaginitis which may not affect female fertility while, the minority of them had PID. In contrast, Bosky (2007) reported that, PID is known to be long-term consequences of sexually transmitted diseases as well as of vaginitis (bacterial vaginosis), pelvic surgery, and other gynecologic procedures that cross the cervix. Also, the findings are not supported by Morse, (2010), who reported that, women who are not treated for PID right away can experience serious complications ranging from infertility to ectopic pregnancy to chronic pelvic pain.

Furthermore, Sexual factors such as frequency of sexual intercourse per week is a predictor variable that might affect the female

fertility while, use of chemicals lubricants for intercourse and use of antiseptic douches immediately after intercourse didn't affect female fertility.

Frequency of sexual intercourse per week is linked with the female infertility. The findings of the study revealed that tenth of the sample had sexual intercourse more than four times per week, more than half of sample had sexual intercourse from 3-4 times/week and, more than one-third of them had sexual intercourse less than three times/week. This is may be related to frequency of sexual intercourse too many (>4 times/week) is linked with premature sperms, while, too less sexual intercourse (<3 times/week) is linked with aging sperm. In spite of frequency of sexual intercourse is from 3-4 times/week is considered within normal (by review) but may be occur at wrong time (not around ovulation period). This finding is in agreement with Stanford, and Dunson (2007) who mentioned that, frequency and timing intercourse can impact on declining fertility rate, especially with low frequency intercourse. In addition, Robinson, and Ellis (2007) reported that, failure to conceive was appeared to be related to mistiming of intercourse. Moreover, Marshburn, Alanis, and Matthews (2009) indicated that timing intercourse is crucial in increasing women chances of conception which increases with the frequency of intercourse around the fertility days although the sperm concentration might be decreases slightly with higher frequency of intercourse.

Unfortunately, use of chemicals lubricants for intercourse, antiseptic douches immediately after intercourse and dyspareunia are not a predictor variable that might affect incidence of female infertility. This is might be due to the minority of the sample (1.3%) using chemicals lubricants for intercourse, Less than one-tenth of them using antiseptic douches immediately after intercourse, and more than tenth had dyspareunia. Agarwal et al, (2008) found that, using of vaginal lubricants during intercourse is not recommended which consequently decreased sperm motility and viability. Also, they added that careful selection of vaginal lubricants is required for women with vaginal dryness to avoid decreasing in sperm motility and viability.

In addition, contradicting finding with the data of Cottrell (2010) who reported that, frequent vaginal douching is associated with adverse reproductive health outcomes as increased the risk of pelvic inflammatory disease, secondary infertility, and ectopic pregnancy. Also, he added that, douching may impact on health because it disturbs the chemical and microbial balance of the vagina and possibly leading to bacterial vaginosis, dyspareunia and other bacterial infections. Moreover, douching may force

pathogens up through the cervix causing uterine infections where organisms are more likely to cause pelvic inflammatory disease, an infection linked with infertility (Boskey, 2007). In the same context, Cottrell (2006) in his study reported that, women who douched monthly were 2.5 times more likely to have a history of bacterial vaginosis than women who did not douche ($p < .001$), and women who douched weekly were 2.75 times more likely to have bacterial vaginosis ($p = .004$). And it concluded that there is an association between vaginal douching and bacterial vaginosis and that is a predispose factor in reducing fertility.

The study concluded that, women with the following profile: older age at marriage, overweight and obese, depending on fatty saturated diet, eat snacks, had history of polycystic ovarian syndromes, had cervicitis, long use of contraceptive methods, and might be at risk for the occurrence of infertility.

Recommendations, based on the findings of the present research, the following recommendations are suggested:

- 1- Raise women's awareness regarding to adopting healthy life style as follow dietary program, and practice exercising.
- 2- Proper treating of underlying medical problems that can impact female fertility.
- 3- Proper timing and frequency of intercourse to maximize achieving pregnancy.
- 4- Further studies are recommended regarding to the following issues:

- The relation between infertility and underweight.

The relation between infertility and chemical douching.

Abstract: Background: For many years, conventional karyotyping has been used as the golden diagnostic tool for t(9; 22) (BCR/ABL) in chronic myeloid leukemia (CML). Recently, there have been an emerging generation of complex translocations and submicroscopic deletions involving BCR & ABL genes in addition to the classic t(9;22), which have a prognostic impact on the course of the disease, and require sensitive and specific molecular techniques for their detection. Objective: The present study aimed to explore the utility of extra signal fluorescence in situ hybridization (ES-FISH) compared to double fusion FISH(DF-FISH) and conventional karyotyping (CK); for detecting the incidence of typical and atypical patterns of BCR/ABL gene rearrangements and clarify their prognostic significance in CML. Subject and Methods: A series of 64 consecutive BCR/ABL⁺ Egyptian CML patients (42 chronic phase, 9 accelerated phase, 13 blastic crisis), were investigated for typical and atypical BCR/ABL rearrangements using extra signal and double fusion FISH probes. Results: ES-FISH and DF-FISH showed higher sensitivity for detection of Philadelphia chromosome (Ph) as a sole anomaly when compared to karyotyping in all phases of CML. ES-FISH was the most sensitive method for detection of ABL deletion (14.2% in chronic phase, 33.3% in accelerated phase, 30.8% in blastic crisis) when compared to DF-FISH and karyotyping. Interestingly, ES-FISH, was the only method capable for detection of minor BCR/ABL rearrangement in 1 patient in blastic crisis phase. On the other hand, DF-FISH showed superiority for detection of BCR deletion. Both DF-FISH and karyotyping were capable of detection of trisomy 9 and variant translocation, while ES-FISH yielded confusing atypical signals regarding them. There was a moderate agreement between D-FISH & ES-FISH (P<0.01), a strong agreement between D-FISH and CK, while no agreement was found between the results of ES-FISH and CK and (P>0.05). In conclusion, karyotyping is mandatory to be applied at diagnosis of CML. ES-FISH is the method of choice for detection of ABL deletions, despite it cannot detect neither BCR deletions nor variant translocations. Karyotyping coupled with ES-FISH are adequate for the diagnosis and therapeutic monitoring of CML with the classical t(9;22) and for cases with ABL deletion.

1. Introduction:

For many years, conventional karyotyping has been used as the sole diagnostic tool for t(9;22) (BCR/ABL). However, it has several limitations that may lead to failure for detecting BCR/ABL gene rearrangements in around 5% of all chronic myeloid leukemia (CML) patients (Deininger *et al.*, 2000). In addition, about 5% of CML cases carry 'masked' translocations that can only be detected by molecular techniques such as fluorescence in situ hybridization (FISH) or reverse transcriptase polymerase chain reaction (RT-PCR) (Druker and Lee, 2005).

The first generation of BCR/ABL single fusion FISH probes detected the fusion gene with high specificity but with a low sensitivity, with a cut off value 6%. A new generation of FISH probes has

been developed known as double fusion (DF-FISH). The developed probe is characterized by high sensitivity and specificity with a cut off value 1.3%. The probe is characterized by spanning wide area, about 450 kb proximal to the ABL gene on 9q34 and in some probes also with distant coverage on 22q (covering both major and minor breakpoint region) (Primo *et al.*, 2003). Despite that, the double fusion FISH probe design does not distinguish between major and minor break point region. Therefore, unable to differentiate between de novo acute lymphoblastic leukemia (ALL) and ALL on top of CML, necessitating the application of polymerase chain reaction (PCR) to overcome this defect (Hirose *et al.*, 2002).

More recently, an extra signal locus specific identifier (LSI) probe was developed to confirm the location of *BCR/ABL* other than 22q1 and to detect both typical and atypical *BCR/ABL* rearrangement, being capable of distinguishing between major (M) and minor (m) break point cluster region. This probe mixture contained directly labeled Spectrum Orange probe that spanned the *ABL* locus at 9q34 and directly labeled spectrum green probe that spanned the *BCR*

locus at 22q11.2. The most frequently detected patterns with the extra signal probe corresponded to typical *BCR/ABL* gene rearrangements involving the *MBCR* (one fusion, one green (*BCR* probe) and two red (*ABL* probe) signals) and the *mBCR* (two fusion, one green and one red signals). The extra signal LSI probe can also detect other atypical interphase FISH (iFISH) patterns as supernumerary Philadelphia (Ph), gain or loss of chromosomes 9 and 22, as well as deletions of 9q and 22q that can occur in *BCR/ABL*⁺ CML, ALL and acute myeloid leukemia (AML) cases (Huntly *et al.*, 2001, Manisha *et al.*, 2010).

This work aimed to explore the utility of extra signal fluorescence in situ hybridization (ES-FISH) compared to double fusion FISH and conventional karyotyping (CK); for detecting the incidence of typical and atypical patterns of *BCR/ABL* gene rearrangements and clarify their prognostic significance in CML.

2. Materials and Methods:

Subjects and Methods

The study was approved by the committee of Medical Research Ethics, Medical School, Ain Shams University; an informed written consent was obtained from all studied subjects. This study was carried out on 64 CML patients who were attending the Hematology Oncology Clinics of Ain Shams University Hospitals.

The patients were classified according to the clinical phase at presentation into three groups:

Group I:

It comprised 42 patients in chronic phase (CP); they were 22 males and 20 females with male to female ratio of 1.1:1. Their ages ranged from 20 - 75 years, with mean age of 49.5 ± 16.2 years.

Group II:

It comprised 9 patients in accelerated phase (AP), they were 5 males and 4 females with male to female ratio of 1.2:1. Their ages ranged from 38 - 61 years, with mean age of 47.6 ± 6.9 years.

Group III:

It comprised 13 patients in blastic crisis (BC) acute myeloid leukemia, they were 5 males and 8 females with male to female ratio of 0.6:1. Their ages

ranged from 28 - 51 years, with mean age of 41.2 ± 8.1 years.

Follow up for the patients was done over a period of 12 months. The patients' outcome was expressed according to The Italian Cooperative Study Group on Chronic Myeloid Leukemia (1994). Good prognosis was identified by complete hematological remission, complete cytogenetic remission and molecular remission. While good response in blastic crisis phase was identified by disappearance of all signs and symptoms of leukemia, bone marrow blast cells <5% and absence of abnormal cells in peripheral blood and cerebrospinal fluid (American Cancer Society, 2009).

Methods:

I. Samples:

One mL of bone marrow (BM) aspirate and 4 mL of venous blood were collected from each patient before initiation of treatment under complete aseptic conditions. Samples were divided as follows:

Two ml PB were collected in a tube containing ethylene diamine tetra acetic acid (EDTA) solution used for complete blood count (CBC) and Leishman stain (done for all cases), and myeloperoxidase stain (applied in BC only). One mL BM and/or 2 mL PB were collected in sterile Lithium heparin coated vacutainer tube for cytogenetic analysis, D-FISH and ES-FISH. Fresh drop of PB was used to prepare PB smear for Neutrophil Alkaline Phosphatase (NAP) score.

II. Conventional Karyotyping (CK):

The steps of conventional karyotyping were performed as previously described (Eberhard, 2001). Most of available metaphases were counted (at least 20), analyzed and karyotyped using Chromoscan Applied Imaging Cytovision 2.7. The banded chromosomes were interpreted according to ISCN 2009.

III. Fluorescent In Situ Hybridization (FISH):

Ø The used probes were:

A) LSI (dual color, dual fusion) probe for t(9;22) (q34;q11) supplied in 20 μ L (vial) (Vysis).

B) LSI dual color *BCR/ABL* ES probe for t(9;22) (q34;q11) supplied in 20 μ L (vial) (Vysis).

The steps and interpretation were performed according to Primo *et al.*, 2003

Cut off value for diagnosis of positive result was 1.3% for D-FISH and 3% for ES-FISH.

IV. Statistical analysis

Data were expressed as mean \pm standard deviation (SD) (range) or as number (%) of cases. Comparison of proportions and means between two

groups was made by using the 2 test and independent t-test, respectively. The Fisher's exact test was used when applicable. Analysis was performed by using the Statistical Package for the Social Sciences (SPSS, version15). The level $P < 0.05$ was considered the cut-off value for significance.

Unpaired (student's) t test was used to test the difference about mean values of lab parameters, results were presented as mean and SD, non parametric data were analyzed using Mann-Whitney test (data presented as median and inter quartile range [IQR])

Kappa test: to measure the agreement between two observers. Strength of agreement (if present) is established according to k value as:

Mild agreement: k value is 0.2 – 0.4, Moderate agreement: k value is >0.4 – 0.6, Strong agreement: k value is >0.6 and <1, and Perfect agreement: k value is 1.

3. Results:

Cytogenetic analysis

Group I (Chronic phase)

Karyotyping was successful in 33/42 patients (78.5%), Out of them, Ph as a sole anomaly was detected in 26/33 (78.7%) patients, while it was associated with additional chromosomal aberrations in 7/33 patients (21.3%), in the form of Ph associated with +8 in 2 patients (6.1%), Ph associated with +9 in 3 patients (9.1%) and Ph associated with del 9q in 2 patients (6.1%). Re-analysis by *ES-FISH* showed Philadelphia chromosome as a sole anomaly in 36/42 (85.8%)(photos 1,2), while associated with ABL deletion in 6/42 patients (14.2%)(photo 3). Interphase FISH signals were atypical and confusing regarding detection of +9 and variant translocations. BCR deletion was not detected in any case. Using *D-FISH*, Ph was detected as a sole anomaly in 36/42 (85.8%), while it was associated with ABL deletion in 3/42 patients (7.1%)(photo 4), out of them both ABL and BCR deletions were detected in 2/42 patients (4.8%), +9 was detected in 3 patients (7.1%). No variant translocations were detected (Tables 2,3)

Group II (Acceleated phase)

Karyotyping was successfully encountered in 7/9 cases (77.8%), of which, Ph as a sole anomaly was present in 4/7 patients (57.1%), and as complex aberration in the remaining 3/7 (42.9%); as Ph associated with 9q deletion in 1 patient (14.3%), Ph associated with +8 in 1 patient (14.3%) and Ph associated with +9 in 1 patient (14.3%). Re-evaluation by *ES-FISH* detected Ph chromosome as a sole anomaly in 6/9 (66.7%) patients. Ph associated with ABL deletion was detected in 3/9 patients (33.3%). No BCR deletion or variant translocations were detected. using *D-FISH* revealed the presence of Ph in 7 /9 (77.8%) patients. Ph associated with +9 was detected in 1/9 patient (11.1%) and associated with both ABL and BCR deletions in the remaining patient (11.1%). No variant translocations were detected (Tables 2,3)

Group III (Blastic crisis)

Out of the 13 patients, 9 (69.2%) showed successful mitosis, in which Ph chromosome was detected as the sole anomaly in 5/9 cases (55.6%), while complex aberrations were detected in the form of complex translocation t(3;9;22) in 1 case (11.1%), Ph associated with +9 in 1 case (11.1%), Ph associated with del 9q in 1 case (11.1%) and Ph associated with +8 in 1 case (11.1%). *ES-FISH* showed the presence of Ph chromosome as the sole anomaly in 8/13 cases (61.5%) (one of them showed minor BCR/ABL) (Photo....). Ph chromosome associated with ABL deletion was detected in 4/13 patients (30.8%) and in the remaining patient double Ph was detected (7.7%). No BCR deletion no variant translocations were detected.Re-evaluation using *D-FISH* detected Ph chromosome as the sole anomaly in 8/13 cases (61.5%). Ph was associated with additional anomalies in the form of Ph associated +9 was detected in 1 patient (7.7%), with ABL deletion in 2 patients (15.4%)(1 out of them showed combined ABL and BCR deletions [7.7%]), double Ph in 1 patient (7.7%) and variant translocation in 1 patient (7.7) (Tables 2,3).

The demographic, clinical features, prognosis and cytogenetic profile of all the studied groups are shown in table 1.

Table (1) Demographic, clinical features, cytogenetic profile and prognosis of all the studied groups

	Chronic (42)		Accel (9)		Blastic (13)		Total (64)

Complex	6	14.2	2	22.2%	5	38.5%	10	15.6%			

Patients in blastic phase showed significant increase in percentages of complex aberrations by ES-FISH (P= 0.05) and highly significant increase by D-FISH (P<0.01) in comparison to other phases.

Table (4): Agreement between CCA, ES-FISH and D-FISH using Kappa test

	CCA				K	P	Sig
	Ph alone (35)		Complex aberration (14)				
	N	%	N	%			
ES FISH							
Ph alone (38)	29	59.2%	9	18.4%	0.20	0.16	NS
Complex aberration (11)	6	12.2%	5	10.2%			
D-FISH							
Ph alone (40)	33	67.3%	4	8.2%	0.69	<0.01	HS
Complex aberration (9)	2	4.1%	10	20.4%			

ES FISH: There was no agreement between CCA and ES-FISH (P>0.05)

D-FISH showed strong agreement with CCA; there was an agreement in 33 sole anomaly and 10 complex (88%) and disagreement 6 cases complex (12%), 2 cases diagnosed as complex by D-FISH but not by CCA ;1 Ph with ABL&BCR, and 1 double Ph. And 4 by CCA (as Ph with +8) not by D-FISH. Exclusion of 15 failed cases by Karyotyping; 9 in chronic phase, 4 in accelerated and 2 in blastic phase (Total 49/64 cases).

Table (5): Agreement between ES-FISH and D-FISH in the whole studied group using kappa test

	ES FISH				k	P	Sig.
	Ph alone (50)		Complex aberration (14)				
	N	%	N	%			
D-FISH							
Ph alone (51)	45	70.3%	6	9.4%	0.48	<0.01	HS
Complex aberration (13)	5	7.8%	8	12.5%			

D-FISH showed moderate agreement with ES FISH; there was an agreement in 45 sole anomaly and 8 complex (83%) and disagreement in 11 cases (17%); 5 cases diagnosed as complex by D-FISH (Ph with +9) but missed by ES-FISH and 6 by ES-FISH (as Ph with ABL) but missed by D-FISH.

Table (6): Prognostic significance of Ph as sole anomaly and of complex aberrations (detected by CCA, ES-FISH and D-FISH)

	Prognosis (n)				P	Sig
	Good (42)		Poor (22)			
	N	%	N	%		
CCA						
Ph alone (35)	30	85.7%	5	14.3%	<0.0001	S
Complex aberration (14)	0	0%	14	100.0%		
Failed (15)	12	80.0%	3	20.0%

4. Discussion:

Several studies have demonstrated that a submicroscopic gene deletion in Ph positive CML is associated with a poor prognosis and reduced response to treatment (Kim *et al.*, 2005). These deletions are proved to be a powerful and independent prognostic factor more potent than the scoring systems of Sokal *et al.* or Hasford *et al.* (Xinh *et al.*, 2006). Molecular techniques are required to demonstrate the presence of these atypical

rearrangements in a sensitive and specific manner (Aoun *et al.*, 2004).

In this work, Ph was detected in all cases with successful mitosis. Ph was detected as a sole anomaly in 35/49 (71.4%) cases, distributed as 26/33 (78.7%) in CP, 4/7 (57.1%) in AP and 5/9 (55.6%) in BP, being highest in CP. The total percentage of Ph chromosome detected as a sole anomaly was midway between that detected by Anoun *et al.*, (2004) and Xinh *et al.*, (2006), where both showed it to be about

83%, and that found by *Reena et al.*, (2006), and *Patel et al.*, (2009), which were 50% and 53.8% respectively. While complex aberration was detected in this study in 14/49 cases (28.6%) as 7/33 (21.3%) in CP, 3/7 (42.9%) in AP and 4/9 (44.4 %) in BP. Complex aberrations detected in the total cases were like that found by *Xinh et al.*, (2006) (20%), but discrepant from that detected by *Anoun et al.*, (2004) and *Reena et al.*, (2006) (11% for both). Having higher percentages of complex aberrations in AP and BP than CP was previously documented by the well established role of additional anomalies in clonal evolution and acceleration of CML (*Reichard et al.*, 2009).

Re-evaluation by ES-FISH improved the ability of detection of genetic aberrations, detecting Ph in 100% of the cases. Ph chromosome was detected as the sole anomaly in 50/64 cases (78.1%), with the peak incidence of 85.7% in CP as expected (36/42 cases). This was consistent with *Moon et al.*, (2007), who found that the incidence of Ph as sole anomaly in CML by ES-FISH is 81%, and close to that found by *Primo et al.*, (2003) (83.3%). This improved ability of detection was evident regarding detection of complex aberrations too, where complex aberrations were detected in 14/64 cases (21.9%), with peaks of incidence in the AP and BP (33.3% and 38.5% respectively). This was consistent with the findings of *Primo et al.*, (2003) and *Moon et al.*, (2007) who found the incidence of complex aberration in the patients of CML studied by ES-FISH to be 16.7% and 19% respectively. This low incidence is due to the minor role of complex aberrations in the pathogenesis of CP of CML, and playing the major role in acceleration and transformation only (*Reichard et al.*, 2009).

The high ability of FISH in detection of specific chromosomal anomalies is that it can be done on interphase nuclei, poorly spread metaphases and well spread metaphases, allowing it to play an important role in such conditions for diagnosis and evaluation of MRD (*Kantarjian et al.*, 1990). Several reports strongly suggest that all FISH data correlate very significantly with chromosome banding data (*Baccarani et al.*, 2008).

The LSI ES-FISH increased this ability by its wide spanning area of 1.5 megabase (*Lim et al.*, 2005). The use of the ES probe reduces the interpretation problems resulting from random juxtapositioning of differently labeled genes producing co-localization signals; and this is the role of the extra signal, it confirms the true positivity of the translocation detected (*Primo et al.*, 2003).

The improved ability of detecting chromosomal anomalies was evident also by using DF-FISH, as Ph chromosome was detected in 100% of cases, as a sole

anomaly in 54/64 cases (84.4%), again with the highest incidence of 92.9% in CP (39/42 cases). The percentage of sole anomaly in our study was the highest detected, despite wide variability among researchers, as the 70% found by *Huntley et al.*, (2001) and *Lim et al.*, (2005), the highly deviant 12.5% by *Loncarevic et al.*, (2002), 81.6% found by *Kim et al.*, (2005) and 77% found by *Siu et al.*, (2009). Complex chromosomal aberrations were detected in 10/64 cases (15.6%), again with the peaks in AP and BP (22.2% and 38.5% respectively). This is matching with the result obtained by *Kim et al.*, (2005) of 18.4%, and with that of *Siu et al.*, (2009) of 22.3%.

Regarding the complex aberrations detected, CCA detected 4/49 (8.2%) cases with ABL deletion (in the form of del9q), ES-FISH detected 13/64 (21.3%), and D-FISH detected 6/64 cases (9.3%) (4 of them were accompanied by BCR deletion). This magnifies the superiority of ES-FISH as a tool for detecting the ABL deletion. In the current work, result of ABL deletion by ES-FISH is midway between the results reported by *Sinclair et al.*, (2000), *Huntly et al.*, (2001) and *Lee et al.*, (2003) (15 - 28.6%).

Primo et al., (2003) stated that ABL deletion is the most common atypical Ph chromosome signal detected, and this agrees with our result, by detecting 13 as ABL deletion from the 14 cases with complex aberration, and is consistent with *Huntly et al.*, (2001), who reported it to be >30% of atypical signals, however, it is much higher than what's found by *Anoun et al.*, (2004) (12%), who found no explanation to this discrepancy from others' results, except the probability of having a relatively low number of cases with an atypical signal in their study.

Results ABL deletion by D-FISH obtained in this work were similar to that found by *Kim et al.*, (2005) and *Siu et al.*, (2009) (6.6 and 9% respectively), higher than that found by *Sinclair et al.*, (2000), *Huntley et al.*, (2001), *Lim et al.*, (2005) (3.6, 2.8, 3.1 respectively), and much less than that found by *Loncarevic et al.*, (2002) (56.2%). This is in agreement with the previously stated wide range of ABL deletion detected. Regarding BCR deletion, D-FISH is the only technique that can detect BCR deletion. In the current study, no BCR deletion alone was detected, as was the situation with *Sinclair et al.*, (2000) and *Kim et al.*, (2005).

Huntley et al., (2001), *Loncarevic et al.*, (2002), *Lim et al.*, (2005) and *Siu et al.*, (2009) reported a wide range of BCR deletion of 0.8, 31.3, 2.1, 3.3 respectively, which were of low values except for the 31.3% reported by *Loncarevic et al.*, (2002), who seem to have a certain form of problem concerning interpretation of the signals, with a high false positive rate, as shown also from the extraordinarily high

value of ABL deletion, which was above the reported range of detection.

ABL and BCR deletions were detected in combination in 4/64 cases (6.2%), which was similar that found by *Kim et al., (2005)* (6.6%), despite the presence of wide range as found by *Sinclair et al., (2000)*, *Huntley et al., (2001)*, *Loncarevic et al., (2002)*, *Lim et al., (2005)* and *Siu et al., (2009)*, whose results were 25, 11.9, Zero, 10.4 and 9% respectively. However, apart from the extreme values of Zero and 25, most of the results were close to that detected in our study.

Trisomy 8 was detected in 4/49 cases (8.2%), and detected by CCA only. This is due to the non directed nature of the CCA, which favors it as the gold standard for the genome wide screen (*Hochhaus et al., 2000*). Trisomy 9 was detected by CCA in 5/49 cases (10.2%), and by D-FISH in 5/64 (7.8%), and they were the same cases. No signal pattern was reported for +9 by D-FISH, but we interpreted the signal in conjunction with the results of CCA.

Supernumerary Ph was detected by ES and D-FISH in 1/64 case (1.5%) and was in BP. This is close to the reported percentage by *Lim et al., (2005)* of 3.1%. They reported one case in AP and one case in BP, which confers to the association made between additional Ph and disease progression, and being one of the major pathways of clonal evolution seen during blast crisis. One case of the 64 cases (1.5%) showed variant translocation by D-FISH, and was detected as complex translocation t(8;9;22) by CCA. However, this issue is not a subject of interest for many researchers at the moment, with well interpreted results obtained only by *Lim et al., (2005)*

Comparing ES-FISH to the CCA and D-FISH, ES-FISH is the only technique that can differentiate MBCR/ABL from mBCR/ABL rearrangements. ES-FISH detected one case (1.5%) of mBCR/ABL. This was compatible with *Primo et al., (2003)* who found mBCR/ABL in 1.5% of CML patients. However, it is important to note that ES-FISH failed to detect variant translocation, the BCR deletions and +9. This is a considerable pitfall of ES-FISH, since these aberrations have a prognostic impact, to be mentioned later.

No agreement was found between the results of CCA and ES-FISH. A strong agreement was found between results of CCA and D-FISH for the results of the overall cases of the study ($P < 0.0001$). This agreement study was done after exclusion of the 15 cases of failed mitosis, and this overestimated the diagnostic power and sensitivity of the CCA, whose main pitfall is the failure of mitosis, and led to the failure of agreement with the ES-FISH. This is consistent with *Patel et al., (2009)* who found a significant and positive correlation between results of

CCA and D-FISH, also, *Baccarani et al., (2008)* stated that several reports strongly suggests that all FISH data correlate very significantly with chromosome banding data (*Schoch et al., 2002*; *Raanani et al., 2004*). There was a moderate agreement between ES-FISH and D-FISH as regards the overall patients ($P < 0.0001$), which simulates the agreements between D-FISH and CCA but with reduced strength, so, despite the lack of direct agreement between CCA and ES-FISH, a trend is noticeable. Results of ABL deletion obtained by D-FISH and ES-FISH showed a moderate highly significant agreement ($P < 0.0001$). This is in favor for ES-FISH in detection of ABL deletions, revealing it as the method of choice for detection of this aberration.

To determine the outcome of the patients, we assessed the hematological, cytogenetic and molecular responses at 1 year after therapy. This is because these responses at 1 year after therapy have been shown to correlate well with survival (*Li et al., 2005*).

As for cytogenetic results, there is an established strong association of major and complete cytogenetic response with improved long term survival with interferon-alpha therapy. These prognostic associations have also been confirmed with imatinib therapy, suggesting that the relationship between response and survival may be independent of the treatment that produced the response (*Kasakyan et al., 2003*). Cases showing complex aberrations by CCA, ES-FISH and D-FISH showed highly significant association with poor prognosis than cases with Ph alone ($P < 0.0001$). This is appropriate with the poor prognostic impact of the chromosomal aberrations mentioned previously.

Detecting such significance by ES-FISH is a good point for it. This is due to the prognostic impact of the ABL deletion, which is the best anomaly detected by ES-FISH, and was the most frequent atypical signal detected in our study. Poor prognosis associated with ABL deletion has been reported by many researches as *Sinclair et al., (2000)*; *Huntly et al., (2001)*; *Lee et al., (2003)* suggested a favorable prognosis.

Regarding mBCR, ES-FISH detected it in case #1 in BP, and it had a moderate prognosis by achieving CHR and MCR, but NMR. Previous studies have shown that mBCR breakpoints develop blast crisis with monocytosis and this agrees with that our single case was in BP, despite failure of judgment by a single case. Adds to the power of ES-FISH is its detection of supernumerary Ph. Detecting supernumerary Ph in BP in our study, and in AP and BP by *Lim et al., (2005)*, confers to the association made between additional Ph and disease progression,

and being one of the major pathways of clonal evolution seen during blast crisis.

Regarding D-FISH, its power is in detecting the BCR deletion, either alone or with ABL deletion. The statistical significance associated between complex aberrations it detected and poor prognosis can be attributed to the combined BCR and ABL deletions, since it was the most frequent atypical signal detected.

The relevance of BCR deletion on prognosis is still a matter of discussion. *Lee et al., 2006 stated that* BCR losses are accompanied by ABL deletion in 70-100% of cases, and might be involved in poor prognosis. Improved survival was once again reported only by *Kreil et al., (2007)*.

Regarding variant translocation, it is inconsistent whether variant translocations confer the same clinical course and outcome as standard ones. Some studies concluded that a variant translocation showed no differences in the disease course of CML and had no effect on prognosis, compared with a standard translocation (*Valencia et al., 2009*). However, some suggested that variant translocations are associated with an adverse outcome (*Loncarevic et al., 2002*). Our study is in favor of the opinion of variant translocation's poor prognosis, despite the low number of cases in our study (one case, #3 in BP), but she was in BP and failed to achieve neither CR nor MR.

In conclusion, karyotyping is mandatory to be applied at diagnosis of CML. ES-FISH is the method of choice for detection of ABL deletions, despite it cannot detect neither BCR deletions nor variant translocations. Karyotyping coupled with ES-FISH are adequate for the diagnosis and therapeutic monitoring of CML with the classical t(9;22) and for cases with ABL deletion

Rural women and micro-credit programs

Azita Zamani

Mahabad Branch, Islamic Azad University, Mahabad, Iran
E-mail: fereshteh12150@yahoo.com

Abstract: Rural women are among those major groups at society who previously were considered less by planners, due to specific reasons in the past. And this problem is more observable at developing countries. While, by looking at women's history of economic and social life, we can find that this great group, continuously have played basic role in forming economic condition of country. This great group consistent with men have had active role at areas of social-economic activities and always have had major part on economic production of society. Nowadays, supporting family supervisor women is adopted by universal society, as politic, economic a social concern and nearly all countries applied related approaches, and however these efforts have resulted in failure, in so many cases . By accessing to wide range of financial tools, families according to their priorities, invest on cases such as costs of education, healthcare, healthy and good nutrition or housing. Applicants for Microfinance resources mostly involved family supervisor women, pensioners, homeless people, frugal workers, small farmers and micro entrepreneurs. Journal of American Science 2011; 7(6):1039-1043]. (ISSN: 1545-1003). <http://www.americanscience.org>.

Keywords: Micro-credit, rural women

Introduction:

Paying part of cost of life by government or charities , establishing forums to analyze family supervisor women's problems , supplying necessary facilities to grow and improve child's life quality and paying facilities to provide sustainable employment , are among most important approaches to support family supervisor women . Paying credit facilities to access sustainable employment with easy terms at limited time, is one of the most important approaches to support family supervisor women. Because alongside supplying their continues needs, their esteem wouldn't be marred. Currently, this approach is used at many countries and positive results have emerged. (Ghaffari, 2000). From 1970, the waves of thought about micro-credits and run of small activity in villages was one of the suitable way get increased for invest improvement in rural occupations.

The said plan because of special grants such as giving loan with low wage and no interest and with long reimbursement could give farmers this opportunity to don't rely usurers and jobber intermediaries. Indeed giving micro-credits to rural women was more effective. Because along agriculture activities which need more investments, the women with using micro-credits couldn't only show their talent in rural production, but also could improve their economic & social empowerments and they could also participate in social activities. (Chabokru et al, 2005).

Women's self-reliance and independency were the outcome of giving credits to women and in some cases were the obstacle of receiving credits by

women which is necessary to explain about them shortly.

As it mentioned before the traditional culture in villages was the reason for weakening women rights and made them oppressed, it is possible that women's self-reliance & financial independency in villages make some crudities (malformation) in the family and village for a short a short time, but we can't disregard it's positive outcome in the social & cultural occasions in the long time, here we will discuss about some of these outcomes (Goetz and Sengupta, 2003)

One of the raised strategy , in order to accelerate investment process and reinforcing financial foundations , and saving , at deprived and rural areas , has been empowering and eradicating poverty of rural societies through efficiency with emphasize on applying micro-credits (Shahnaj and Sajedur, 2009). Micro-loans as useful tool to fight against poverty and starvation, has proven its capabilities and values to develop these areas. These tools have ability to change and improve human's life, especially poor peoples. Micro loans , saving accounts , and giving various bank services , cause this belief in low income and poor family that , by accessing to these services , their income will increase ,so they can protect themselves against barriers of unexpected problems and their current level of life and also invest on nutrition , housing and their children's education.(Varzgar and azizi, 2001)

Accessing to these conditions is among main goals of third millennium program (i.e. eradicating absolute poverty of human societies).

Nowadays micro-credits and supplying micro financial resources, has changed human's life and

cause to revive different societies at poorest and richest countries of world, so that we can see growth in human's power to access to common financial services. By accessing to wide range of financial tools, families according to their priorities, invest on cases such as costs of education, healthcare, healthy and good nutrition or housing.

Applicants for Microfinance resources mostly involved family supervisor women, pensioners, homeless people, frugal workers, small farmers and micro entrepreneurs. These people are divided into four groups: Poor, very poor, relatively poor and vulnerable poor.

Whenever repayment afford, bond terms and accessing to data, in this classification will change, in order to supply sustainable financial needs of various clients, procedures and operation structures will be developed. (Fami, 2001)

Generally, in most countries, micro finance sources are considered for poor women. By women's access possibility to finance services, they committed to loan and ensure its repayment and preserve their saving accounts and also enjoy insurance cover. Supplying programs for micro financial resources have strong message for families and societies. Most of qualitative and quantitative studies and researches have proven that accessing to financial services; will improve women's conditions in family and society. Women's confidence has increased and they are aware of their abilities. (Banihashem, 1999)

Thus, it has proven that supplying financial services for poor peoples is powerful tool to decrease poverty so that make them able to establish finance, increase income and decrease vulnerability against economic pressures.

1- Preferment of women role and their social place:

Women's financial self-reliance can increase the women's social role & place in the villages. In the new condition some of their assignment roles could change to acquisitive roles. The women should use of all their power & energy for doing their acquisitive roles. Thus they can find active view to different functions. The people & groups could increase their social place in the village with improving their social role. If their role and social place preferment be accompanied with the increasing of social intelligence & knowledge, it can have more effect culturally. (Amiri, 2000)

2- Increasing self-confidence:

Self-reliance in different life aspects can increase people's self-confidence. Rural women who are financially independent can live peacefully. With decreasing their problems in life, their self-confidence will increase. And self-confidence is one

of personality & mentally condition for being success in life.

3- Family consistency:

At the first, it seems that rural women's financial independency is not acceptable by their husband and this causes some gaps in their family's relations. But little by little these problems will be solved by increasing the rural people's knowledge. Usually poverty is one of the reasons which will destroy or decrease family's consistency. Women by working and having income can help their husband & family. (Fakhraee, 1381)

4- Change in family's relation:

The rural women with having a job and financial independency can change the viewpoint of people who live in villages and cities and they will not look at the rural women as a weak and dependent people. But also their title and place will increase among their families. So by changing people's view to the women, gently we can see some changes in their family's relation which will have respect to the women's right. By increasing women's knowledge and by introducing new rural institution which give financial & authority service to the women, their stimulus (motivation) for reaching their social rights will increase and they try more than before (Amiri, 2000).

5- Making patriarchy weak in the family:

Gently, with changing family's relation in the villages and by increasing rural people's knowledge, we can make the men and women's right equal and also we won't have patriarchy in the family, although patriarchy has historic and olden root in our villages but with improving women's position and increasing their cultural and social knowledge we can destroy patriarchy in the rural families. (Chowdhury, 2005).

6- Population and family adjustment:

The practitioner women's view about the number of the children is different; studies show that practitioner women are interested to fewer children to the house keeper women.

By decreasing families in the village and women's financial independency we are more hopeful to adjust family's population in the future because villages have important role in the population increase in Iran. (Shaditalab 75).

The role of micro-credits in rural economy:

The first application of micro-credit was about 20 years ago with the establishment of Grumman Bank in Bangladesh. This bank, providing credit for the poor (particularly women as 94% of its clients are them), has managed to increase income and economic

welfare. Now the program is running in most parts of world especially Asia, Africa and Latin America. One interesting point is that unlike prior perceptions, the poor covered by micro-credit programs has been very successful in paying back their loans.

In the countries that credits are provided in a proper financial manner, not only it has increased production and income but also it has encouraged poor to save a part of their income. These savings can be an important support for the institutes providing micro-credits and can be a financial base for more loans and all these result in institutes' financial dependence.

With the new way of micro-credit payments, in addition to covering poor's financial needs, a combination of other services and facilities are available for them; such as saving accounts, educational services, and cooperation possibilities (Goetz and Sengupta, 2003).

If rural women could provide a job for them by getting credits, loan and other financial convenience, through their income they can get self-reliance or financial independency and we will see social, cultural & economic change in village. The question here is that if these changes have positive or negative aspects in the village? It's natural that every change in social phenomenon has both positive and negative aspect, but which is Important here is that which aspect is more than the other and it depends to different condition in various societies. In our rural society there is an especial social & cultural kind that it's outcome maybe different and in some case inconsistent. With these actions rural women could be in idealistic economic condition and they could live with out dependency to their husband's income. In most of the villages in Iran there is patriarchy in the families which is not acceptable for the most of the rural people and groups. When rural women became financially independent, it's acceptable to see its cultural & social outcomes.

Giving the right that women make decision, independency to their family, increasing the cultural knowledge among them& making relation with new institutions, having independency in making decision about marriage, occupation, migration & something like this are the right that women have got it.

Conclusion:

Many studies have proven that women's access to mentioned facilities may improve their conditions in family and society; it also helps them feel more self-confident and makes them aware of their own abilities. Thus providing micro-credit services for the poor in society is a powerful tool to reduce poverty and so that they are able to create assets, earn more money and become less vulnerable against the economic pressure. Of about 1.3 billion poor in the world there are 900

million poor women, this obviously shows that poverty has a feminine face. According to UN's development fund, 10% of world's income and less than 10% of world's assets belongs to women. While a majority of them never possess the capital needed for their activities, women still play an important role in the economic development of country. Therefore women draw the micro-credit policy maker's attention more than others. Choosing women as the main target of micro-credit plans is an effective strategy to eradicate poverty; because their income will upgrade the family welfare; furthermore earning money improves their social status. In some countries this choice is influenced by society's attitude and culture (Araghzadeh, 2002).

For instance founder of Grumman Bank of Bangladesh, Mohammad Yunes, has stated that: "women have plans for themselves, their children, and their family life; they always have an overlook while men just look for fun" to explain why 94% of their clients are women.

Women's access to micro-credits have shown that their income benefit to improve their family and provide livelihood. In addition to all these another reason of women being the target of micro-credit plans is that women have higher loan recovery rates. Totally, expanding women's access to micro-credits may lead to many useful results which in economy is mentioned as "virtuous spiral"; because their access to micro-credits results in family welfare and in a broader point it'll improve community's welfare and shall be increased welfare this process is repeated.

In researches that conducted by Nanda (2004) became clear that women participation in credits programs had positive effects on their demand about health care. Fiona Steele and et al (2008) in researches that conducted as called "influences of credits programs on empowering women at Bangladesh", found that women who joined to credits programs, have participated in more educational programs and have married with more educated men and also they have saved more and they had more cash.

Shahnaj and Chaudhury (2009) in research as "credits and its role on empowering women" concluded that there is meaningful relation between attending in credits programs and empowering women, at economical dimensions.

Jameela (2010) presented that credit programs has shown lot of affects on empowering women so that has increased their social, politic and economic ability.

Thus it is obvious that credits programs and its educational and empowering programs can be affective on social, humane and economic development or rural society, if it be associated with proper and gradual practices and base on reciprocal communications principles and apply opinion of local society.

A study conducted by Chabokru et al (1384) shows the crucial importance of micro-credits for farmers who do

not possess physical financial assets (land, building, livestock, well...) and work in agricultural sector because of environmental conditions (such as living in a village) or because it's their ancestral occupation.

So today, women's participation in sustainable economic, social, and cultural development in rural areas is not optional but an essential matter. Those communities that have not seriously considered the necessity of participation faced failures and delayed community's development, welfare and security process. In any community, village, or social group, broad participation of every women in decision-making and any other matter related to national or local development programs, is a key variable in social sciences and in the last few decades, it has interested many scholars of socio-economic and especially cultural issues, and is considered as one of the most fundamental democratic rights of women in a society. As we know in a popular participation, all people are given the opportunity to participate in planning and decision making for their society and for their own future. When in practice women feel that they can be involved in planning, policy making and deciding or solving problems in the society certainly they'll feel more solidarity and become more interested in social, economic, and cultural development programs.

Function of micro-credit in increasing rural women's participation

Mehdi Nazarpour

Marvdasht Branch, Islamic Azad University, Marvdasht, Iran

E-mail: hossein11070@yahoo.com

Abstract: Being high and low of each one is depended on various conditions and terms so it is varied from one society to another society. In Iranian rural societies, cultural and social context is such that, consequences of these phenomena maybe being different and sometimes contradictory. However these actions caused that women stand in good economic condition and also gain self reliance and rely themselves with no help from husbands, but dominant cultural space on villages may create some disorders. At most of villages in Iran, patriarchal with all features dominate and women's financial self reliance may not being pleasant for some human and rural groups. When women gain financial independence in villages, impacts and social and cultural consequences would emerge. Journal of American Science 2011; 7(6):1044-1048]. (ISSN: 1545-1003). <http://www.americanscience.org>.

Keywords: micro-credit, participation, rural women

Introduction:

Paying credit facilities to access sustainable employment with easy terms at limited time, is one of the most important approaches to support family supervisor women. Because alongside supplying their continues needs, their esteem wouldn't be marred. Currently, this approach is used at many countries and positive results have emerged. (Ghaffari, 2000). Aforementioned plan, due to containing special advantage such as giving accessible loan with low commission fee and no interest rate and also long-term repayment, could provide chances for many farmers to release from dealers and broker jobbers. In this approach, giving micro-credits to rural women seems more effective. because alongside agricultures activities that needed more investments , women by enjoying of very micro-credits not only could create remarkable creativities in rural productions but also gained worthy economic and social abilities , and even improved their field of social presence , well . (Lahsaeizadeh, 2000).

If rural women can work through receiving credits , loan and others finance facilities at favorite jobs and live through earned income (as it called "self-reliance and independence") , so undoubtedly we would see changes in social, economic and cultural relations of village.

Here, Basic issue is that if changes happened following of these events in villages, have positive aspects or negative? Naturally, every change in institutions and social phenomena has both positive and negative dimensions. (Farghdan, 2001)

Increasing Suffrage, lack of relying on vast patriarchal families, increasing cultural acknowledgment, relation with newer institutions, having intellectual independence, making decision

for marrying, occupation, emigration and etc are those rights that they gain. gaining aforementioned

rights by women in context of cultural and social framework followed some changes that maybe lead to disfunctions and even create disorders and abnormalities at traditional , familial and kinship relations that dominated on villages (Fakhraee 2002)

What that performing credits programs, has made in recent years, was on broad outlook with purpose to access to same results as above findings.

Thus, in one inclusive outlook , it is possible to use micro-credits programs to solve those issues which involved with rural women's economic limitations , so that lead them toward social empowerment, in the context of economic growth(Rahmani andalibi, 2001) .

Micro-loans as useful tool to fight against poverty and starvation, has proven its capabilities and values to develop these areas. These tools have ability to change and improve human's life, especially poor peoples. Micro loans , saving accounts , and giving various bank services , cause this belief in low income and poor family that , by accessing to these services , their income will increase ,so they can protect themselves against barriers of unexpected problems and their current level of life and also invest on nutrition , housing and their children's education.(Varzgar and azizi, 2001)

Accessing to these conditions is among main goals of third millennium program (i.e. eradicating absolute poverty of human societies).

In micro-credits programs other than offering and distributing micro loans, there are also small savings and deposits so that they are designed as form of saving-credit programs. The existing term in phrase "micro-credits" points to two basic concepts that is due to dominant perspective on this approach. First term (i.e. credits) points to rural areas and lack of access for many villagers to formal resources that are one of their major problems. And at system of micro-

credits, are tried to decrease poor families' access barriers to credit sources and also to increase effectiveness of these markets. Second term (i.e. micro) emphasize on deficiency of development, according to classic economist's method. Emphasizing on concept of "micro" means revising recommendations of market economy at rural society's development.

Rural women participation:

As most men leave the village to work in town, women provide much of the agriculture force in the area. In recent years the situation has been more considerable as rural migration to town is getting more. In most Iranian villages women's population is more than men. According to FAO's reports, in some African regions, for 60% of families, women are responsible for supervising family. Even for cases that men are the direct responsible of production affairs, women's role in family economy can't be denied just because they don't get paid. Although these efforts appear to register in none of official statistics, they easily replace some other activities with significant financial value.

Studies by FAO show that more than half of the world's crops are collected by women. According to estimates, 1.3 billion of world's poor are women, thus the slogan "poverty has a feminine face" is spread worldwide.

Given that in many parts of the world, the production potential of women is not used properly, a cost-benefit study by the World Bank shows that investing on women in developing countries will be more profitable than any other investment. In addition to financial benefits of this huge force, its ancillary results will also be useful. The ancillary benefits of women's employment include: lower population growth and children mortality rates (Navab Akbar, 1997).

Rural women are a big part of productive force and in developing countries third to half of them are supervising households; as a result they face numerous problems, such as:

- Lack of access to social and health facilities
- Various daily chores inside and outside the home
- Men's skill and increase of women's responsibility
- Lack of professional to educate women

Around the world and in Iran, the issue related to female employment, especially in rural areas (which is a manifestation of participation), is not unemployment but unpaid employment; because all the unpaid work done by women at home, such as cleaning, washing, nursing, social affairs, agriculture and livestock,... are encountered as non-economical activities; While visible economic sector cannot continue to exist without this invisible sector's goods and services. On the other hand, rise of industrial system and expansion of factory job all over the world, attracted men to these economic systems and this has given men an objective vision; Whereas, the majority of women, due

to working alone at home have got a subjective vision. Now, as women enter labor market and start to participate, they'll become objectified; because the work system will encourage them to think like men. Being more around the house and their local area will help both men and women in terms of subjectivity and objectivity (Arab-Mazar and Jamshidi, 2005).

Thus the issue of women's participation has important effects, including:

- Acceleration of plans implementation
- Realization of people's every day needs with cooperation and consultation
- Increasing efficiency and reducing functional expanses of projects
- Creating opportunities for talent realization and scientific activities
- Creating sense of solidarity and cooperation
- Increase social and personal awareness
- Women, sharing ideas in decision-making and determining their own destiny
- Participation of women as an important factor and a major power to achieve development

Therefore, according to preceding discussions and importance of women's participation in future plans, it's of great importance to study and recognize the factors affecting their participation in social activities of rural area (Fakhraee, 2002).

Major obstacles to women's participation:

Considering society's current conditions and the issues mentioned above, major obstacles which result in women's less participation can be classified as follows.

1- Social and cultural barriers

Sociologically, women in third world countries- especially in rural areas- believe to be dependent on men.

The thought is deeply attached to their historical beliefs. Thereupon they never share ideas while decision-making or planning. As some sociology and politic experts stated, it's the reason they have developed "the silence culture" and they never let themselves to comment on, or participate in planning.

In addition, customs and prejudices that they have been trained with, indirectly affects women's participation. Such ideology of knowing a sex to be lower than the other is a crippling disease that causes a big part of mental and power sources of community remain disadvantaged. These are all prejudice emphasizing on men's value and denying those of women (Changizi Ashtiani, 2003).

2- Economical barriers

One of the factors indicating development progress is how and how much different classes of society participate in vital activities. Although importance of women's participation has always been completely apparent, the appropriate balance between men and women in different fields is not yet established in our country. As women can only possess a limited sort of jobs and also they always have the smaller share of each job opportunity, they are not able to compete in labor market. What's more, mostly they do not own the capital needed for economical participation, so providing personal credits can solve their problem in some extent.

3- Structural barriers

In fact, in most countries, governing power, marketing and production conditions and some values related to them, create serious structural barriers to women's participation. According to United Nations' research institute of second development program, these structures are anti-participation; because they lead to unequal access to the control of wealth and social status. They cause failure of many national-regional innovations encouraging participation, and finally make a small group be responsible for everything and we won't have the beneficial results associated with women's participation. The structure determines the conditions of participation and reacts strongly to any renovation. Its objective is to keep women in their position as a labor. Labor market divides the jobs in workshops and factories in a way that some occupational fields are only for women and some other only for men. Men are chosen to be the administrator in all professions and it's assumed that women are not interested in or not able to handle these positions. Thus, in practice the world of production and work is subject to gender discrimination.

4- Educational barriers

Apparently, one essential factor for development is education. Studies indicate that compared with men and boys women and girls do not have sufficient access to education. Some of the factors effecting women's access to education are:

1. Great need of parents to their daughters as labor force
2. Lack of access to educational experts and planners
3. Lack of schools or proper places for girl's education

4. Mixed classes for boys and girls and rural bias on this issue
5. Education expenses
6. Lack of attention to the importance of girls' roles
7. Social, cultural and traditional beliefs about girls
8. Early marriage

Report by UNICEF, claims that literacy rate of women in developing countries is two third of men's, and of about 860 million illiterate adult worldwide, 640 million are women who never had the possibility to go to school or have left school unfinished (Bakhshoodeh and Salami, 2005).

5- Political and organizational barriers

In third world countries, women face with many obstacles for participation in decision making, planning, implementation, and evaluation of projects related to country's developing plans. Although, the structure of the country play an important role in making suitable conditions for participation in different areas, but because they have focused plans and such decisions are made by public organizations and official systems, usually the potential force of participation in society will be palled and in practice, participation will face serious obstacles and problems. A focused government always encourages focused official structures. Such a structure is a major barrier to women's participation. They control structures and systems resource allocation and information and knowledge people need to participate in social activities, besides they never let people and especially women control all these. So it's apparent that such programs are either not comprehensive or it's facing problems because designers are not aware of the realities in their community.

6- Barriers related to wife-mother role

UNICEF reports indicate that women's work hours is 25% longer than men's; because a large number of them work at home to produce livelihood products without payment.

The main role of all women in each society is the role of mother and wife; therefore every other matter such as their employment is subject to these roles. Possibility of finding a job (as administrator or in a lower rank) for a girl is affected by various factors including educational level and their socialization method as a child. They have always been thought that they are not

identical to boys in terms of social privileges or social status. Emphasize on the roles of mother and wife may make women think there is no need to promote their social status and in the other hand society will not provide necessary facilities for their development. In this situation they are prevented from studying and schooling. This issue will still be a problem after they are married. It should be noted that with women getting paid, total household's welfare improves; because field studies claim that all women earning money, spend their income on their family and particularly children's needs.

So we should mention that not only participation is a woman's civil right but also it will make her more autonomic, and she'll become more creative and innovative.

Discussion and results:

Women's access to micro-credits have shown that their income benefit to improve their family and provide livelihood. In addition to all these another reason of women being the target of micro-credit plans is that women have higher loan recovery rates. Totally, expanding women's access to micro-credits may lead to many useful results which in economy is mentioned as "virtuous spiral"; because their access to micro-credits results in family welfare and in a broader point it'll improve community's welfare and shall be increased welfare this process is repeated.

In researches that conducted by Nanda (2004) became clear that women participation in credits programs had positive effects on their demand about health care. Fiona Steele and et al (2008) in researches that conducted as called "influences of credits programs on empowering women at Bangladesh", found that women who joined to credits programs, have participated in more educational programs and have married with more educated men and also they have saved more and they had more cash.

Shahnaj and Chaudhury (2009) in research as "credits and its role on empowering women" concluded that there is meaningful relation between attending in credits programs and empowering women, at economical dimensions.

Maybe the main challenges that threaten credits associations, is lack of necessary emphasizes on social dimensions and on reinforcing their basics, that practically cause that this social foundations lose its efficiency soon and practically changed to unsuccessful institution.

Fiona Steele and et al (2008) in researches that conducted as called "influences of credits programs on empowering women at Bangladesh", found that women who joined to credits programs, have participated in more educational programs and have married with more

educated men and also they have saved more and they had more cash.

Ellen and her Colleagues (2009) used approach called it "credits and education at Bolivia, Ghana, Honduras, Mali and Thailand". This approach looks for empowering women through financial services with education. In this approach, women get familiar with importance of credits through education and extension and also familiar with ways to access it through establishing different groups.

Ruhal Amin and others (2010) found that those who joined credit funds had more ability rather than those who didn't.

Jameela (2010) presented that credit programs has shown lot of affects on empowering women so that has increased their social, politic and economic ability.

Thus it is obvious that credits programs and its educational and empowering programs can be affective on social, humane and economic development or rural society, if it be associated with proper and gradual practices and base on reciprocal communications principles and apply opinion of local society.

A study conducted by Chabokru et al (1384) shows the crucial importance of micro-credits for farmers who do not possess physical financial assets (land, building, livestock, well...) and work in agricultural sector because of environmental conditions (such as living in a village) or because it's their ancestral occupation.

So today, women's participation in sustainable economic, social, and cultural development in rural areas is not optional but an essential matter. Those communities that have not seriously considered the necessity of participation faced failures and delayed community's development, welfare and security process. In any community, village, or social group, broad participation of every women in decision-making and any other matter related to national or local development programs, is a key variable in social sciences and in the last few decades, it has interested many scholars of socio-economic and especially cultural issues, and is considered as one of the most fundamental democratic rights of women in a society. As we know in a popular participation, all people are given the opportunity to participate in planning and decision making for their society and for their own future. When in practice women feel that they can be involved in planning, policy making and deciding or solving problems in the society certainly they'll feel more solidarity and become more interested in social, economic, and cultural development programs.

Workplace Violence - A Survey of Diagnostic Radiographers in Ismailia Governorate Hospitals, Egypt

Reem A Abbas^{1*} and Selim F Selim²

¹Community, Occupational and Environmental Medicine Department, Faculty of Medicine, Zagazig University, Egypt.

²Radiology Department, Suez Canal Authority Hospital, Ismailia City, Egypt.

*reemabbasabbas@yahoo.com

Abstract: Violence in hospitals is becoming more frequent and more aggressive worldwide. Radiographers, as members of the frontline hospital personnel are at increased risk of workplace violence. So, this study aimed to determine the magnitude and the nature of workplace violence towards radiographers in hospitals, to identify its risk factors, and to study its impact on victims. All diagnostic radiographers in Ismailia Governorate Hospitals (n=123), except those who were on extended leaves or who had less than one year clinical experience (n=22), were invited to complete a standardized questionnaire designed specifically to study workplace violence in the health sector. Out of 101 radiographers, 94 agreed to participate in this study (response rate = 93.1%). The majority of the participants (79.8%) had experienced workplace violence of any kind. Verbal abuse was the most common type. Patients' relatives were the main perpetrators. Most of violent incidents were not reported. Easy public access, crowding and noise, understaffing, and long waiting times, were the potential factors contributing to hospital violence. Many negative consequences on the victims' psychological status and work performance have been revealed. It could be concluded that workplace violence towards diagnostic radiographers is a significant problem in hospitals; thus, effective preventive strategies should be designed and implemented.

[Reem A Abbas and Selim F Selim. Workplace Violence - A Survey of Diagnostic Radiographers in Ismailia Governorate Hospitals, Egypt. Journal of American Science 2011;7(6):1049-1058].(ISSN: 1545-1003). <http://www.americanscience.org>.

Keywords: Workplace violence; diagnostic radiographers; health sector.

1. Introduction:

Workplace violence has become an alarming phenomenon worldwide. It is a major contributor to death and injury in many parts of the world (Merecz *et al.*, 2006). In the United States, homicide is the third leading cause of death in the workplace. In the European Union, 2% of the labor force has been subjected to physical violence at work. However, recent surveys all over the world showed that current figures represent only the tip of the iceberg. So, many international organizations have made efforts to recognize workplace violence in various service sector industries and establish guidelines for its prevention (ILO, ICN, WHO & PSI, 2003 and Chappell & Di Martino, 2006).

Workplace violence affects many occupational groups, especially those in the health industry where violence is becoming a feature of everyday clinical practice (Warsaw & Messite, 1996; Jones & Lyneham, 2000; Lyneham, 2001 and ILO, 2003_a). Frontline hospital personnel such as nurses and radiographers are particularly at higher risk; where patients, patients' relatives, employers, supervisors, or coworkers are usually the possible sources of violence. Poorly designed working environment and long waiting times can trigger violence (Kwok *et al.*, 2006; Kris *et al.*, 2009 and MFL Occupational Health Centre, 2009).

Workplace violence at the health sector can be in the form of physical assault, homicide, verbal abuse, bullying/mobbing, sexual and racial harassment, and psychological stress. It can occur as one single incident or repeated small incidents which together create severe harm including immediate and long-term disruption to interpersonal relationships and to the whole working environment (ILO, ICN, WHO & PSI, 2003).

The global cost of workplace violence is enormous due to causes including; illness, disability and death, absenteeism and sick leaves, accidents, turnover of staff, and reduced work performance (Chappell & Di Martino, 2006).

Although interest in workplace violence in the health sector has grown considerably within the developed world, it still appears to be a "hidden and tertiary issue" in many developing countries (Kamchuchat *et al.*, 2008). Moreover, most hospital surveys have been conducted to determine the magnitude of the problem among nursing staff (Jones & Lyneham, 2000; Kwok *et al.*, 2006 and Abbas *et al.*, 2010). Unfortunately, workplace violence directed at radiographers and other frontline health sector personnel has rarely been researched in developing countries including Egypt, thus the real size of the problem in the health sector is largely unknown till now. So, this study was conducted to

determine the prevalence, nature, and sources of workplace violence among radiographers in Ismailia Governorate hospitals, to identify risk factors contributing to violent incidents, and to study their negative impact on victims in order to suggest appropriate preventive strategies.

2. Methods:

Study design and setting:

This cross-sectional study was conducted throughout the period from November 2010 to February 2011 in all Ismailia Governorate Hospitals (n=11) including; Ministry of Health (n=8), Health Insurance, Suez Canal University, and Suez Canal Authority Hospitals.

Study population:

The total number of diagnostic radiographers in Ismailia Governorate Hospitals at the time of the study was 123, out of them 18 were on extended leaves and 4 were excluded as they had less than one year clinical experience. Thus, 101 radiographers were invited personally to participate in this study.

Ethical issues:

Consent from the Ethical Committee of Scientific Researches in Zagazig Faculty of Medicine was obtained. Also, permissions were obtained from the managers of the hospitals before conducting the study. Moreover, informed consents were obtained from all the participants while interviewing them.

Tools of the study:

All participants were personally interviewed using a questionnaire based mainly on "workplace violence in the health sector - country case study – questionnaire" (ILO, ICN, WHO & PSI, 2003) and other relevant questionnaires (Anderson, 2002 and IAPA, 2007). The questionnaire was translated into Arabic after being modified according to the Egyptian culture, nature of work of diagnostic radiographers, and working conditions in the Egyptian health sector. This questionnaire composed of five main parts;

Part one: included demographic data of the participants such as; age, sex, marital status, current workplace, common work location, clinical experience years, work shift, and staff number present in the same work setting during most of work time.

Part two: included hospital violence description such as; types and common sources of violence as well as victims' responses to violent incidents.

For the purpose of this study, workplace violence was defined as any act in which a person is abused, threatened, intimidated or assaulted during

work, including commuting to and from work, involving an explicit or implicit challenge to safety, well-being or health. Moreover, four types of violence experienced within the health sector were categorized (ILO, ICN, WHO & PSI, 2003; Winstanley & Whittington, 2004; Caruana, 2005; Kris *et al.*, 2009 and MFL Occupational Health Centre, 2009);

- 1) Physical assault: the use of physical force against an individual involving physical contact, such as beating, kicking, slapping, stabbing, shooting, pushing, biting, pinching, and sexual assault, regardless of whether or not an injury was sustained.
- 2) Verbal abuse: the use of words which are personally insulting, such as generally abusive spoken obscenities and foul language, or indicating a lack of respect for the dignity and worth of an individual.
- 3) Threatening behavior: any action that involves signs of violence indicating intention to harm, such as the intention to throw a chair, cause a fight or to verbally threaten an individual.
- 4) Sexual harassment: any unwanted behavior of a sexual nature, including verbal or physical, which is offensive to an individual or for the perpetrator's own sexual gratification.

Part three: included data about participants' knowledge, opinion, and satisfaction regarding workplace violence prevention and reporting procedures.

Part four: included data about factors contributing to hospital violence such as; security measures defects (insufficient security guards and lack of panic alarms), hospital environment and workplace design defects (obstructed escape routes, easy public access, insufficient lightning, noise, and crowding), work organization and training defects (understaffing in work shifts, long waiting times, long working hours and work overload, poor communication, and insufficient training of staff regarding predicting and confronting workplace violence), and factors related to hospitals' location and patients' characteristics (prevalent violence and crimes in the region and alcohol drinking and addiction).

Part five: included data about the negative impact of violent incidents on victims including manifestations and consequences of post-traumatic stress disorder such as; repeated disturbing memories, sleeping difficulties, concentration difficulties, repeated headache, frustration/depression, aggression/anxiety, job dissatisfaction, lack of willingness to work, increased sick leaves, disturbed social relations, need for psychic counseling, alcohol

consumption/addiction, and suicide attempts (Bisson, 2007).

Data management:

Data were computerized and statistically analyzed using SPSS version 19 (IBM, 2010). Chi-squared and Fisher exact tests were used for categorical qualitative variables. Odds ratios (OR) with 95% confidence intervals (CI) were also estimated.

3. Results:

Prevalence and demographic risk factors of workplace violence

Ninety four out of 101 radiographers agreed to participate in this study with a response rate of 93.1%. They were distributed in Ismailia Governorate hospitals as follow; 60.6% in the ministry of health, 21.3% in the Suez Canal University, 12.8% in the Suez Canal Authority, and 5.3% in the Health Insurance. The common work location for all of them was the Radiology Department. The majority of the participants (79.8%) had experienced workplace violence of any kind. Moreover, the present study revealed that young age (< 45 years), male sex, low clinical experience (< 10 years), and rotating work shifts were not significantly associated with workplace violence. Alternatively, married radiographers and those who were working most of their times with staff number ≤ 5 were significantly at higher risk for workplace violence compared to single radiographers and those who were working with > 5 staff members [OR (95% CI) = 10.2 (2.35-45.83) and 6.34 (1.17-35.3), respectively] (Table 1).

Workplace violence description and victims' responses

Respondents who had experienced violence (n=75) were allowed to choose multiple types of workplace violence, verbal abuse was the most common type (98.7%), followed by threatening behavior (46.7%), and physical assault (38.7%); while, sexual harassment was rare (1.3%) (Figure 1).

Violence victims were allowed to choose multiple workplace violence sources, patients' relatives were the main source (100%), followed by patients themselves (50.7%); while, minority of victimized respondents had suffered violence from managers/supervisors/heads of departments as well as from their colleagues (8% and 2.7%, respectively) (Figure 2).

Victimized respondents were allowed to indicate multiple responses on this issue; where it

was revealed that the majority of them reported the incidents to senior staff/head of department/manager, called security/police, or tried to warn the attacker (85.3%, 77.3%, and 58.7%, respectively); while, minority of them tried to defend themselves verbally or physically, completed an incident form, or asked help from colleagues (14.7%, 5.3%, 2.7%, and 1.3%, respectively). On the other hand, none of them ignored the incident, pursued prosecution, or completed a compensation claim (Table 2).

Participants' knowledge, opinion, and satisfaction

The majority of respondents (97.9%) considered most of violent incidents are preventable. Moreover, 93.6% of them knew about the existence of hospital violence reporting procedures. However, 60% of respondents with occupational violence experience were not satisfied about the existing reporting and investigation procedures (Table 3).

Factors contributing to workplace violence

Respondents were allowed to choose multiple risk factors of hospital violence, the majority of them (92.6%, 81.9%, 72.3%, 71.3%, and 67%, respectively) considered easy public access, crowding and noise, understaffing, insufficient security staff, and long waiting times as major risk factors. However, lower proportions (47.9%, 44.7%, and 37.2%, respectively) considered that prevalent violence and crimes in the region, insufficient staff training, alcohol drinking and addiction, and long working hours/work overload as important risk factors. Other factors such as, insufficient lightning, lack of/obstructed escape routes, poor communication, and lack of panic alarm/cell phones were not considered to be major contributing factors for hospital violence (Table 4).

Impact of workplace violence on victims

Violence victims (n=75) were allowed to choose multiple manifestations and consequences of post-traumatic stress disorder; where the majority of them complained of lack of willing to work, repeated headache, job dissatisfaction, and concentration difficulties (78.7%, 73.3%, 66.7%, and 50.7%, respectively); while, lower proportions reported aggression/anxiety, frustration/depression, increased sick leaves, repeated disturbing memories, disturbed social relations, and sleeping difficulties (49.3%, 32%, 24%, 21.3%, 16%, and 12%, respectively). While, none of them reported psychic counseling need, alcohol consumption/addiction, or suicide attempts (Table 5).

Table (1): Prevalence and demographic risk factors of workplace violence towards the studied diagnostic radiographers.

<i>Variables</i>	<i>Total participants (n = 94)</i>	<i>Experienced violence (n = 75)</i>	<i>OR (95% CI)</i>
Age (years)			
< 45	72 (76.6%)	59 (81.9%)	1.7
≥ 45	22 (23.4%)	16 (72.7%)	(0.45 – 5.76)
Sex			
Male	73 (77.7%)	60 (82.2%)	1.85
Female	21 (22.3%)	15 (71.4%)	(0.49 – 6.31)
Marital status			
Married	81 (86.2%)	70 (86.4%)	10.2
Single	13 (13.8%)	5 (38.5%)	(2.35 – 45.83)*
Experience years			
< 10	44 (46.8%)	36 (81.8%)	1.27
≥ 10	50 (53.2%)	39 (78%)	(0.41 – 3.95)
Work shift

Figure (2): Frequency distribution of victims according to the reported sources of workplace violence.

Table (2): Victims' responses to workplace violence

<i>Responses</i>	<i>Violence victims (n =75)</i>
Reported to senior staff/head of department/manger	64 (85.3%)
Called security/police	58 (77.3%)
Tried to warn the attacker	44 (58.7%)
Tried to defend verbally	11 (14.7%)
Tried to defend physically	4 (5.3%)
Completed an incident form	2 (2.7%)
Asked help from colleagues	1 (1.3%)

Table (3): Participants' knowledge, opinion, and satisfaction regarding workplace violence prevention and reporting procedures.

<i>Knowledge and opinion</i>	<i>Total participants (n = 94)</i>
Considering violent incidents are preventable	92 (97.9%)
Knowing of existing workplace violence reporting procedures	88 (93.6%)
<i>Satisfaction level</i>	<i>Violence victims (n = 75)</i>
Not satisfied	45 (60%)
Satisfied to some extent	29 (38.7%)
Very satisfied	1 (1.3%)

Table (4): Factors contributing to workplace violence.

<i>Contributing factors</i>	<i>Total participants (n = 94)</i>
Easy public access	87 (92.6%)
Crowding and noise	77 (81.9%)
Understaffing	68 (72.3%)
Insufficient security staff number	67 (71.3%)
Long waiting times	63 (67%)
Prevalent violence and crimes in the region	45 (47.9%)
Insufficient staff training	42 (44.7%)
Alcohol drinking and addiction	35 (37.2%)
Long working hours/work overload	35 (37.2%)
Insufficient light (inside/outside)	25 (26.6%)
Lack of/obstructed escape routes	18 (19.1%)
Poor communication	16 (17%)
Lack of panic alarm/cell phone	10 (10.6%)

Table (5): Impact of workplace violence on victims.

<i>Negative impact</i>	<i>Violence victims (n =75)</i>
Lack of willing to work	59 (78.7%)
Repeated headache	55 (73.3%)
Job dissatisfaction	50 (66.7%)
Concentration difficulties	38 (50.7%)
Aggression/anxiety	37 (49.3%)
Frustration/depression	24 (32%)
Increased sick leaves	18 (24%)
Repeated disturbing memories	16 (21.3%)
Disturbed social relations	12 (16%)
Sleeping difficulties	9 (12%)

4. Discussion:

The present study showed that the majority of the studied radiographers (79.8%) had experienced workplace violence of any kind. Closely similar results were revealed by many international studies, where more than 50% and even up to 100% of health care providers in hospitals experienced violent incidents (Lyneham, 2001; May & Grubbs, 2002; Wells & Bowers, 2002; Hegney *et al.*, 2003; Uzun, 2003; Mayhew & Chappell, 2005; Kwok *et al.*, 2006 and Ryan & Maguire, 2006). Moreover, the result of the present study confirms those of previous similar studies conducted on radiographers in Ireland (Healy *et al.*, 2002) and Hong Kong (Kris *et al.*, 2009), however in those studies slightly lower proportions of the respondents reported experience of workplace violence (63% and 61%, respectively). On the contrary to our results, much lower prevalence of workplace violence (27.7%) was reported by two Arabian studies conducted on nurses in Ismailia Governorate hospitals and primary health care centers, Egypt (Abbas *et al.*, 2010) and on primary health care workers in Al-Hassa, Saudi Arabia (El-Gilany *et al.*, 2010). These discrepancies in the results could be attributed to the differences between countries, health service level, health care professions, and patients' characteristics. Moreover, hospitals' characteristics including their geographical distribution, size, and the number of population being served have a major role in determining the magnitude of workplace violence; where the lower the education level and socioeconomic status of the population as well as the larger the hospital and the greater the number of patients being served with very high levels in services such as Accident and Emergency and Psychiatry the higher the incidence of workplace violence (Hesketh *et al.*, 2003; Ryan & Maguire, 2006; Gascón *et al.*, 2009 and Kris *et al.*, 2009). Furthermore, most of these studies varied in their definition of workplace violence and the recall period (Kwok *et al.*, 2006).

The present study revealed that young age (< 45 years), male sex, low clinical experience (< 10 years), and rotating work shifts were not significantly associated with workplace violence. Alternatively, married radiographers and those who were working most of their times with staff number ≤ 5 were significantly at higher risk for workplace violence compared to single radiographers and those who were working with > 5 staff members [OR (95% CI) = 10.2 (2.35-45.83) and 6.34 (1.17-35.3), respectively]. The result of the present study agrees with those of other studies, where it was suggested that the role relationship with patients, not the gender was the predictor of violence (Binder & McNeil, 1994; Healy *et al.*, 2002 and Kris *et al.*, 2009). Moreover, our

result confirms that of another study conducted on radiographers in Hong Kong where low experience didn't increase the risk of workplace violence (Kris *et al.*, 2009). On the contrary to our results, young age and shorter duration of employment were revealed to be the determinants of violence towards radiographers (Healy *et al.*, 2002) and nurses (Chou *et al.*, 2002 and Chen *et al.*, 2009). Regarding shift work, the finding of the current study is consistent with that of a previous similar one, which revealed that violent incidents may occur at any time thus hospitals should allocate at least one experienced radiographer in each shift (Kris *et al.*, 2009). Alternatively, other studies found that night shifts pose more risks than other time periods and have recommended that more experienced staff should work during these periods (Ayranci, 2005 and Caruana, 2005). Moreover, the results of the present study disagree with those of an Egyptian study conducted on nursing staff, where males, those who were commonly working in night shifts, and those in a place crowded with colleagues were significantly more exposed to violence. Moreover, being single posed no higher risk of exposure to violence than being married (Abbas *et al.*, 2010). These discrepancies may be due to the variations between those studies and the present one regarding the cut off point of the experience years and the age of the participants as well as the differences between nurses and radiographers regarding educational and training years and job tasks. Furthermore, marriage can lead to increased risk of violence, where it has been suggested that accumulation of stress and tension from familial and societal problems in demanding health occupations can contribute to emerging violence (ILO, 2003_b).

In the present study, verbal abuse was the most common type of violence (98.7%), followed by threatening behavior (46.7%), and physical assault (38.7%); while, sexual harassment was rare (1.3%). These findings are closely similar to those of the Hong Kong study, where verbal abuse was the most common type of violence (96.7%), followed by threatening behavior (34.1%) and physical assault (20.9%); while sexual harassment was also rare (3.2%) (Kris *et al.*, 2009). Similarly, an Australian survey involving radiographers revealed that the most frequent violence categories were verbal abuse, followed by threats of physical violence [Caruana, 2005]. Moreover, different research studies conducted in Israel, Hong Kong, Turkey, England, Spain, and Egypt found that verbal abuse ranged from 43% to 91% ; while physical violence ranged from 5.3% to 33% (Carmi-Iluz *et al.*, 2005; Kwok *et al.*, 2006; Celil *et al.*, 2007; Whittington & Shuttleworth, 2008; Gascón *et al.*, 2009 and Abbas *et al.*

al., 2010). Thus, it was suggested that despite the variable range of the reported workplace violence there is a consensus that the most commonly encountered type is verbal abuse (Atawneh *et al.*, 2003; Uzun, 2003 and Mayhew & Chappell, 2005).

The present study revealed that in all violent incidents patients' relatives were the main perpetrators. Moreover, a significant portion of violence and abuse was committed by patients (50.7%); while, managers/heads of departments/supervisors as well as colleagues represented minor sources for workplace violence (8% and 2.7%, respectively). The findings of the present study partially agree with those of other studies, where patients followed by their relatives were the major sources of workplace violence towards nurses and radiographers. Moreover, colleagues, seniors, managers, and doctors were not the sole perpetrators of workplace violence (Hesketh *et al.*, 2003; Kwok *et al.*, 2006; Kris *et al.*, 2009 and Abbas *et al.*, 2010). Our findings could be attributed to the easy hospital access of patients' relatives as well as to the job tasks of diagnostic radiographers in most hospitals that requires not only close contact with patients, as in positioning, but also dealing with their upset and worried relatives as described by another similar study (Kris *et al.*, 2009). Moreover, it was reported that patients may be a source of violence due to an emotive state such as anxiety, frustration, and anger due to restriction from usual activity, unrealistic expectation of the service, or being in pain (Caruana, 2005). Also, our results agree with those of another study, where it was suggested that internal violence shouldn't be overlooked as it may contribute to some incidents (Lee, 2006).

Regarding victims' responses towards workplace violence, the majority of them reported the incidents to senior staff/head of department/manager, called security/police, or tried to warn the attacker (85.3%, 77.3%, and 58.7%, respectively); while, minority of them tried to defend themselves verbally or physically, completed an incident form, or asked help from colleagues (14.7%, 5.3%, 2.7%, and 1.3%, respectively). On the other hand, none of them ignored the incident, pursued prosecution, or completed a compensation claim. Health care providers' responses towards violence partially differed in other studies, where the most common response was taking no action; the next common response was either to get help from co-workers/security or trying to defend themselves verbally; then warning the attacker; followed by reporting to senior staff. While, in those studies and ours, only a minority of the victims completed an incident form. The researchers of those studies suggested some factors that may contribute to such

response including; being afraid of what others would think of them, perceiving violence as part of their jobs, believing that reporting is not helpful, or insufficient training not only in recognizing signs of violence, but also in managing violent situations (Hesketh *et al.*, 2003; Ayranci, 2005; Caruana, 2005 and Kris *et al.*, 2009). The current study revealed a surprising result regarding this issue, where the majority of violence victims responded in a more correct way and a minority of them had self-defeating attitudes compared to those in the previously mentioned international studies. Our finding could be attributed to the higher prevalence of workplace violence towards the studied group that helps them in gaining better experience in predicting and confronting violent incidents.

In this study, the majority of respondents (97.9%) considered most of violent incidents are preventable. Moreover, 93.6% of respondents knew about the existence of hospital violence reporting procedures. However, 60% of violence victims were not satisfied about the existing reporting and investigation procedures. These findings partially agree with those of another study, where over half the respondents (56%) considered violence to be preventable; while, only 40% of them knew of existing guidelines on violence in their own hospitals and a minority (23.3%) found the support from their department was adequate (Kris *et al.*, 2009). Moreover, in an Egyptian study, over half the exposed nurses (55.8%) thought that violence events were preventable (Abbas *et al.*, 2010). The findings of the present study were also supported by those of a previous survey study, where most radiographers were not satisfied with the management procedures as they felt that the management impress that the patients have rights, but this does not extend to the staff (Caruana, 2005).

Many environmental and patients-related risk factors of workplace violence were largely explored in many studies (Chen *et al.*, 2009). Moreover, the results of several studies revealed that violence in the health sector is influenced by underlying structural and situational risk factors (Viitasara & Menckel, 2002). Regarding this issue, the results of the current study revealed that the majority of the respondents (92.6%, 81.9%, 72.3%, 71.3%, and 67%, respectively) considered easy public access, crowding and noise, understaffing, insufficient security staff, and long waiting times as major risk factors. However, lower proportions (47.9%, 44.7%, and 37.2%, respectively) considered that prevalent violence and crimes in the region, insufficient staff training, alcohol drinking and addiction, and long working hours/work overload as important risk factors. Other factors such as, insufficient lightning,

lack of/obstructed escape routes, poor communication, and lack of panic alarm/cell phones were not considered to be major contributing factors for hospital violence. These findings partially agree with those of other studies, where long waiting hours, crowding, poor security, poor communication, understaffing, alcohol and other substance abuse (Tiihonen *et al.*, 1997 and Wallace *et al.*, 1998), patients with psychological problems (Nijman *et al.*, 2002), and work overload and long working hours were considered as potential provoking factors for violent events (Healy *et al.*, 2002; Di Martino, 2003; Ayranci, 2005; Caruana, 2005 and Kris *et al.*, 2009). So, the findings of the current study highlighted some important defects in hospitals' environment and work design, work organization, and security measures as potential factors contributing to workplace violence.

Although, recognizing the severity of workplace violence problem is essential, further investigation of the impact of such violence can benefit the whole profession (Kwok *et al.*, 2006). Thus, the present study investigated this issue and revealed that considerable proportions of violence victims had reported one or more of post-traumatic stress manifestations and consequences such as; lack of willing to work, repeated headache, job dissatisfaction, concentration difficulties, aggression/anxiety, frustration/depression, increased sick leaves, repeated disturbing memories, disturbed social relations, and sleeping difficulties. While, none of them reported psychic counseling need, alcohol consumption/addiction, or suicide attempts. These findings support those of other studies, where it was revealed that violence at work can trigger a range of psychological and emotional outcomes in victims such as anxiety, anger, fear, depression, increased stress, and sleep disturbances (Di Martino, 2003; ILO, 2003; Winstanley & Whittington, 2004 and Kris *et al.*, 2009). Moreover, many studies reported the negative impact of workplace violence on job satisfaction, willingness to work, eagerness in the profession, and work performance which in turn directly had negative impact on patient care and consequently the effectiveness of the health care system (Arnetz & Arnetz, 2001; Hesketh *et al.*, 2003 and Kris *et al.*, 2009).

5. Limitations of the study:

The present study is a cross-sectional one that aimed to obtain a generalized overview about workplace violence towards diagnostic radiographers in hospitals throughout the whole years of their clinical profession, thus it would have been subjected to recall bias. Moreover, despite of using standardized and clear definitions for different types

of workplace violence, the feeling of being abused is very subjective.

6. Conclusions and recommendations:

Findings of this study revealed that diagnostic radiographers in hospitals are at high risk of workplace violence. The most common type of violence was verbal abuse. However, threatening behavior and physical assault were not uncommon. Patients' relatives were the main perpetrators in all violent incidents. Although, the majority of respondents knew about the existence of hospital violence reporting procedures, most of violent incidents were not reported as most of victims were not satisfied about the existing reporting and investigation procedures. Hospital environment and work design defects, poor work organization, and insufficient security measures were the potential factors contributing to workplace violence. Many negative consequences of workplace violence on the victims' psychological status and work performance have been revealed.

So, there is an urgent need to control workplace violence in hospitals, which requires active collaboration between managers and health care providers in identifying and assessing the risk for violence and developing a workplace violence prevention policy and program in consultation with the hospital health and safety committee. The policy should outline reporting and incident investigation as well as ways for eliminating or mitigating the risk of violence including; improving working environment, workplace design, work organization, and styles of management; providing greater opportunities for training of radiographers to address workplace violence; and providing victims with counseling and employees assistance programs. Moreover, continuous research efforts must be supported to improve the safety of health personnel worldwide.

Competing interests:

The authors declare that there are no competing interests. Moreover, this research paper was financed by the authors of the study.

²Department Public Health, Faculty of Medicine, Cairo University

mailbox_mcs@yahoo.com

Abstract: The aim of this study was to assess smoking behavior of medical workers in the National Cancer Institute (NCI), their knowledge and attitude towards smoking. This is a cross-sectional survey with anonymous self-administered questionnaires for physicians and nurses. It included three sections; 1) demographic data, 2) questions about knowledge of smoking hazards, religious and lawful aspects and 3) questions regarding smoking status and attitude towards quitting and prohibiting smoking in work and public places. Participants were 246; 185 responded (75.2%). Smokers constituted 25.4% of the sample. Responding current smokers were 37. The majority of smokers reported previous trials to quit, mainly due to health concern (73.3%). All workers know that smoking is harmful to health, the majority were positive about the hazard of passive smoking as well. Ever-smokers showed a negative attitude towards total prevention of smoking at workplace; however, current smokers react positively to smoking restriction in work and public places, about 2/3 stop immediately when confronted by a stop smoking sign. Twenty-seven workers (73%) reported less smoking in response to restriction. A large percent (73%) smoke in presence of nonsmokers, however nearly 92% respond to a colleague's demand to stop smoking. It is concluded that smoking remains a common habit among medical works in the NCI in spite of having a good knowledge about its hazards and direct contact with smoking victims. We should search for the suitable approach for this category of smokers to motivate them to quit other than talking about health hazards. [Manar M. Moneer, Nargis A. Labib and Maissa K. Noaman. **Smoking behavior, knowledge and attitudes among medical workers in the national cancer institute, Cairo University.** Journal of American Science, 2011;7(6):1059-1064]. (ISSN:1545-0740). <http://www.americanscience.org>

Keywords: Smoking, Knowledge, attitude, medical workers.

1. Introduction

Smoking and the use of other tobacco products has been linked to a wide range of detrimental health outcomes including cancer, cardiovascular disease and respiratory illness (WHO, 2008). The risks affect not only smokers themselves but other individuals who are exposed to second-hand tobacco smoke or "environmental" tobacco smoke (ETS); the latter has been shown to contribute to a number of adverse health effects including increased risk of respiratory and cardiovascular illnesses (WHO, 2007). The Egypt Demographic and Health Survey (EDHS) 2008 (El-Zanaty & Way, 2009) reported a prevalence of use of tobacco products of more than 40 percent of men and less than 1 percent in women. Among men, 35 percent reported smoking cigarettes only while 9 percent said they used other forms of tobacco, in some cases in addition to cigarettes.

It is widely recognized that most smokers attempt to quit smoking many times, but the struggle against the smoking addiction is very difficult and the odds in favor of a successful attempt to quit smoking do not exceed 5% (Hughes et al., 2004).

In their workplace, workers in the National Cancer Institute (NCI), Cairo University are

confronted by a substantial number of patients suffering from oncological conditions directly linked to smoking. This may put a higher burden on these workers more than others working outside the institute concerning smoking habit. This study adopted a questionnaire method to assess the smoking behavior among medical workers in the NCI and to determine their knowledge and attitude towards smoking.

2. Participants and Method

This study involved all medical workers attending the day of interview and accepting participation in the study in all medical departments of the NCI during the year 2008. Anonymous self-administered questionnaires were handed to workers in these departments involving physicians and nurses. A pilot study was conducted on 20 workers to assess the questionnaire (clarity, time consumption and different responses) and it was modified accordingly. The questionnaire includes the following sections; the first part of the questionnaire concerned demographic data and the second part included questions about knowledge about smoking hazards, religious and lawful aspects.

The third part was directed towards current smokers and ex-smokers. It involved questions regarding the number of smoked cigarettes, the date of starting smoking cigarettes, smoking cessation attempts, smoking in work place and smoking in the presence of non-smokers and in the presence of children. The following part was concerned with attitude and behavior towards smoking and restrictions at public and work places. Nicotine dependence was assessed using the heaviness of smoking index which is a short form of Fagerstorm test for nicotine dependence (Heatherton et al., 1989).

Statistical analysis:

Data was analyzed using SPSSwin statistical package version 15. Chi-square test (or Fisher's exact test) was used to examine the relation between qualitative variables. For quantitative data, comparison between two groups was done using student t-test. All tests were two-tailed. A p-value < 0.05 was considered significant.

3. Results

Number of participants was 246; 185 of them responded to the questionnaire (75.2%). Of the respondents, 54.6% were men, 41.6% younger than 30 years. One of the respondents did not complete the questionnaire. Table (1) summarizes the characteristics of respondents. Ever-smokers constituted 25.4% of the sample (n = 47). Current smokers (n = 38) included 2 "Shisha" smokers in addition to the 36 cigarette smokers, and similarly 5 of the 9 former smokers were using "Shisha". Table (2) compares ever-smokers and nonsmokers. It is worth to mention here that the nursing staff interviewed were mainly males (n = 23). Ever-smokers were mainly males (91.5%). Twenty percent of ever-smoker physicians were surgeons.

One of the smokers did not proceed after the questions of current smoking status. Thus, tables (3) and the following show the results obtained from 37 smokers. Age at starting smoking was rather young (19.7 ± 4.3 yrs). Engaging in a new friendship was a trigger to start smoking in nearly 60 percent of smokers.

The majority of smokers reported previous trials to quit smoking, several times in one third of cases. Health concern was the main motive to try to quit smoking habit (73.3%), to improve health or physical activity or as medical advice. The main cause of failure to quit is lacking a solid will (Table 4). Health concern was also the main motive to quit smoking in 7 of the 9 former smokers (77.8%).

All workers know that smoking is harmful to health, the majority were well-acquainted about the hazard of passive smoking as well. There was no

significant difference between ever-smokers and non-smokers concerning health, religious and lawful issues of smoking (Table 5).

As other public places, NCI is considered by law a smoking-free place. Ever-smokers showed negative attitude towards the restriction principle and punishment of outlaws. They encourage assigning special places for smoking in the hospital (Table 6).

Current smokers react positively to smoking restriction in work and public places, about 2/3 stop immediately when confronted by a stop smoking sign. Twenty-seven workers (73%) reported less smoking in response to restriction. A large percent (73%) smoke in presence of nonsmokers, however nearly 92% respond to a colleague's demand to stop smoking (Table 7).

Table 1: Characteristics of Respondents (n = 185)

Age, years (Mean±SD)	34.8±11.1
20-30	77 (41.6%)
31-40	63 (34.1%)
41-50	14 (7.6%)
>50	31 (16.8%)
Gender (Male/Female)	101/84
Marital Status	
Married	125 (67.6%)
Not Married	60 (32.4%)
Work	
Physicians	152 (82.2%)
Nurses	33 (17.8%)
Smoking status	
Current smoker	38 (20.5%)
Former smoker	9 (4.9%)
Never smoker	138 (74.6%)

4. Discussion

The current study revealed that proportion of smoking among medical workers in the National Cancer Institute (NCI) was 25.4%. This is lower than figures reported in the general population (40%) (El-Zanaty & Way, 2009). In 2002, smoking prevalence in Egypt ranged from 18.3% (35% in males), as reported by WHO, to 27.2% (48.5% in males) (Youssef et al., 2002). In 1993, an Egyptian study performed in Ismailia reported a 34.4% prevalence of smoking among physicians (Riskalla et al., 1993). Prevalence in males (42.6%) was comparable while in females (4.8%) was very much higher than the prevalence in general population (< 1%). In the current study, there was a very high proportion of smokers (66.7%) among nursing staff. Those smoking nurses were mainly males, just one female was smoker.

Table 2: Comparison between ever-smokers and nonsmokers concerning demographic characteristics

	Ever Smokers (n = 47)	Non Smokers (n = 138)	p value
Gender			
Male	43 (42.6%)	58 (57.4%)

Table 5: Knowledge of smoking habit among medical workers in the NCI

Statements	Ever Smokers (n = 46), No. (%)	Non Smokers (n = 138), No. (%)	p value
Smoking is harmful to health	47 (100)	138 (100)	1.000
Passive smoking is harmful to health	44 (93.6)	136 (98.6)	0.105
Maternal smoking during pregnancy increases the risk of pregnancy-related diseases and congenital anomalies	46 (97.7)	132 (95.7)	0.250
Passive smoking increases the risk of lung disease in smokers' children	43 (91.5)	131 (94.9)	0.276
Knowing about religious "Fatwa" about smoking	39 (83.0)	170 (91.9)	0.101
Knowing about the Law prohibiting smoking in health facilities	40 (85.1)	103 (74.6)	0.139

Table 6: Opinion of medical workers in the NCI about smoking restriction in workplace

	Ever Smokers (n = 46), No. (%)	Non Smokers (n = 138), No. (%)	p value
The presence of special places for smoking	22 (46.8%)	32 (23.2%)	0.002
Smoking during rest hours in a special place	11 (23.4%)	14 (10.1%)	0.022
Total prevention of smoking at work place	8 (17.0%)	66 (47.8%)	< 0.001
Setting up smoking regulations with punishment	6 (12.8%)	56 (40.6%)	< 0.001
There should be no smoking restrictions at work	6 (12.8%)	1 (0.7%)	< 0.001

Table 7: Attitude of current smokers towards smoking restriction in work and public place (n = 37)

Reaction to "No Smoking" sign while smoking	
Stop immediately	25 (67.6%)
Move to another place to smoke	8 (21.6%)
Continue to smoke	3 (8.1%)
Wait to be asked to stop	1 (2.7%)
Smoking in the presence of non-smokers	27 (73.0%)
Smoking at work-place	29 (78.4%)
Reaction to smoking restriction	
Smoke less	27 (73.0%)
Try to Quit	3 (8.1%)
No change	7 (18.9%)
Response to a colleague's demand not to smoke	
Respond	34 (91.9%)
Ignore	3 (8.1%)
Reaction to institute support to quit smoking (n = 36)	
Respond	32 (88.9%)
Ignore	4 (11.1%)

Effect of working with cancer patients, with a considerable percentage suffering from smoking-related fatal diseases, was not an enough motive to lower the prevalence of smoking to a minimum. Very high percentage of nurses (66.7%) and female physicians (4.8%), relative to the general population, still stick to this habit. Nevertheless, the main motive to quit smoking in former smokers and to try to quit among current smokers is health concern (73.3%). We hope more of the current shift to the former side in future.

This hope is supported by high frequency of quitting trials (81.1%). The main obstacle is lack of dominant will to stop. Impression of loss of concentration, headache and irritability were reported as causes of failure (36.7%) despite the fact that nicotine dependence is mostly light to moderate (94.5%).

Twenty percent of ever-smoker physicians in the current study were surgeons. A Chinese study reported a high smoking prevalence (45.2%) among male surgeons (Yao et al., 2009). Another study in China (Zhou et al., 2010) reported smoking rate (26%) among physicians of all specialties comparable to ours and other studies in this country (Jiang et al., 2007; Cui et al., 2007). A polish study, on the contrary reported lower prevalence of 11.3% (Czajkowska-Malinowska et al., 2008). They reported that 25.1% of physicians were ex-smokers. A Greek study showed an overall prevalence of smoking of 38.6% among physicians (Sotiropoulos et al., 2007).

Health professionals in Bosnia and Herzegovina had a high rate of smoking among physicians (40%) and nurses (51%), compared to other European countries (Hodgetts et al., 2004). Italian general practitioners in 2000 recorded smoking rate of 28.3% (Pizzo et al., 2003). In the Netherlands, smoking

prevalence was 25% in physicians and 44% in nurses (WHO, 1997). In the United States, while nurses had a smoking prevalence of 18% in 1991, physicians had a low prevalence of 3.3% (Nelson et al., 1994).

A postal survey of smoking habits among 1,623 Finnish physicians revealed a prevalence of regular smoking of 10% in males and 6%. This study showed a decrease of daily smoking from 24% in males and 17% in females along 2 decades (Jormanainen et al. 1997).

The current study proved the expected fact that the majority of medical workers were well oriented about the health hazards of active and passive smoking on the smoker and his family. Also, religious opinion that smoking is prohibited was a clear fact for 83% of smokers, as was the law restricting smoking in health facilities. Although physicians and nurses do not lack necessary knowledge to refuse smoking habit, but unfortunately this was not enough. This was reflected in their opinion about smoking restriction in workplace; 17% of ever-smokers refuse total smoking prevention.

However, the attitude towards smoking restriction in work and public places is rather encouraging. The majority of current smokers stops immediately in response to a "No Smoking" sign (67.6%) or move to other place (21.6%). Smoking restriction drives 73% of smokers to smoke less. Most of smokers submit to colleagues' demand to stop smoking. These chasing efforts have to continue to fruit more trend towards quitting. Tough efforts are needed as a majority still did not mind to smoke in presence of nonsmokers (73%) and in workplaces (78.4%).

Physicians should be influential role-models to the general population. The high smoking prevalence provides an unhealthy role-model for patients. Near

90% of medical workers were ready to respond to the institutional support to quit smoking.

Constraints: a large number of smokers especially females did not easily accept participation. Most of the non-respondents were smoking physicians.

In conclusion, smoking is still a common habit among physicians and nurses working in the NCI in spite of having a good knowledge about its hazards and direct contact with smoking victims. We should search for the suitable approach for this category of smokers to motivate them to quit other than talking about health hazards.

Abstract: Carboxymethyl chitosan (CMC), which is a water-soluble derivative of chitosan, it has attracted much attention as a new biomedical material. **The aim** of the current study was to evaluate the chemopreventive effects of CMC against Carbon tetrachloride (CCl₄)-induced genotoxicity and alterations in gene expression in male Balb/c mice. **Materials and Methods:** Sixty male Balb/c mice were divided into six groups included the control group; the group treated orally with CCl₄ (0.5 ml/kg b.w) for three doses at 48 h intervals and the groups treated orally with CMC (140 and 280 mg/kg b.w.) alone for three weeks or in combination with CCl₄. **The results** indicated that treatment with CCl₄ resulted in increased caspase-3 activities, induction of micronucleus (MnPCes), frequencies of sister chromatid exchanges (SCE's), total chromosomal aberrations in bone marrow, DNA fragmentation percentage in liver, comet formation in liver and bone marrow, over expression in *bax* and down expression in *Bcl-2*. CMC at the two tested doses succeeded to induce a significant improvement in all tested parameters in a dose dependent fashion. Moreover, CMC itself was safe at the tested doses. It could be concluded that CMC is a promise candidate against genotoxicity.

[Sekena H. Abdel-Aziem, Aziza M. Hassan, Asmaa S. Salman, Ahmed I. Waly, Mosaad A. Abdel-Wahhab.

Genetic alterations and gene expression profile in male Balb/c mice treated with carbon tetrachloride with or without carboxy-methyl chitosan. Journal of American Science 2011;7(6):1065-1076]. (ISSN: 1545-1003). <http://www.americanscience.org>.

Key words: genotoxicity, Carboxymethyl chitosan

1. Introduction

Chitosan (COS) is a modified, natural carbohydrate polymer derived by deacetylation of chitin [poly- β -(1 \rightarrow 4)-N-acetyl-D glucosamine], a major component of the shells of crustacean such as crab; shrimp; crawfish and the 2nd most abundant natural biopolymer after cellulose (No and Meyers 1995). During the past several decades, COS has received increased attention for its commercial applications in the biomedical, food, and chemical industries (Li *et al.*, 1992). In 2005, shrimp-derived COS was approved as GRAS (generally recognized as safe) by USFDA based on the scientific procedures for use in foods in general, including meat and poultry, for multiple technical effects (No *et al.*, 2007). COS has been approved as a food additive in Korea and Japan since 1995 and 1983, respectively (Weiner 1992; KFSA 1995). COS has attracted notable interest due to its biological activities such as antimicrobial (No *et al.*, 2002; Zheng and Zhu, 2003), antifungal (Roller and Covill, 1999), antitumor (Qin *et al.*, 2002), and hypocholesterolemic functions (Sugano *et al.*, 1992). The antimicrobial activity of COS against a range of food borne filamentous fungi, yeast, and bacteria has attracted attention as a potential food preservative of natural origin (Sagoo *et al.*, 2002).

COS also protect normal cells from apoptosis challenged by exogenous stimuli (Chen *et al.*, 2006), and apoptosis induced by serum starvation in human astrocytes (Koo *et al.*, 2002). Moreover, COS are known to exert good anti-oxidative activities in either cellular studies or cell-free assay (Je *et al.*, 2004; Mendis *et al.*, 2007) and many COS derivatives were synthesized and their antioxidant activity was assessed accordingly (Esumi *et al.*, 2003; Sun *et al.*, 2004; Xing *et al.*, 2005). Although the effectiveness of COS for its ability to

enhance quality and shelf life of foods has been reported by numerous workers, the information about the chemoprotective effects is still limited. Therefore, the aims of the current study were to evaluate the protective role of carboxymethyl chitosan (CMC) against the development of comet images during apoptosis induced by CCl₄ and to establish a correlation between induction of apoptosis and comet formation through the measurements of several assays such as activation of caspase 3, and expressions of apoptosis related genes such as bcl-2 and bax, micronucleus formation, DNA fragmentation and cytogenetic analysis.

2. Material and Methods

2.1. Materials:

2.1.1. Chemicals

Pharmaceutical grade chitosan (90 % deacetylated) was obtained from the Naval Research Laboratory (Washington DC, USA). Carbon tetrachloride (CCl₄) was purchased from Merck/Schuchardt (Darmstadt, Germany). A protease inhibitor cocktail was purchased from Roche (Mannheim, Germany), Trizol, fluorogenic substrates (7-amino-4-methylcoumarin N-acetyl-L-aspartyl-L-glutamyl- L-valyl-L-aspartic acid amide [Ac-DEVD-AMC], Bcl-2, Bax and β -Actin were obtained from Life Technologies (Grand Island, NY, USA). Superscript II reverse transcriptase Fermentas kits, Bromodeoxyuridine, propidium iodine, Dimethyl sulfoxide (DMSO), fetal calf serum, normal melting point agarose, low melting point agarose, ethidium bromide and Triton X-100 were purchased from Sigma Chemical Co. (St. Louis, MO, USA). All other chemicals and reagents used were analytical grade.

Synthesis of Carboxymethyl Chitosan (CMC):

Chitosan (2 g) was alkalinized in NaOH (8 g) for 12 h in a 50-50 mixture of deionized water and isopropanol (20 ml). After heating the mixture to 60 °C, monochloroacetic acid (8 g) was dissolved in isopropanol (2 ml) and slowly added to the solution over 30 min. After 6 h the reaction was quenched by adding ethanol (50 ml) to the solution. The resulting CMC was repeatedly rinsed in ethanol and vacuum-dried until the pH of the filtered solution was neutral. The products were dissolved in water and centrifuged to separate the unreacted chitosan; the water soluble portion of the sample was removed, precipitated in ethanol and vacuum-dried. The sample was then placed in an oven at 50 °C to dry.

2.1.2. Experimental animals:

Eight-week-old male Balb/c mice (25 \pm 3 g) were obtained from the Animal House Colony, Giza, Egypt and were maintained *ad libitum* on standard lab diet (protein: 160.4; fat: 36.3; fiber: 41 g/kg and metabolizable energy 12.08 MJ) purchased from Meladco Feed Co. (Aubor City, Cairo, Egypt). Animals were housed in a room free from any source of chemical contamination, artificially illuminated and thermally controlled, at the Animal House Lab.,

National Research Centre, Dokki, Cairo, Egypt. After an acclimatization period of one week, the animals were divided into six groups (10 mice/group) and housed in filter-top polycarbonate cages. All animals were received humane care in compliance with the guidelines of the Animal Care and Use Committee of the National Research Centre, Dokki, Cairo, Egypt.

2.2. Methods:

2.2.1. Experimental design

Animals within different treatment groups were maintained on their respective diets for 3 weeks as follows: group 1, untreated control; groups 2 and 3 treated orally with CMC at 140 and 280 mg/kg b.w. respectively for three weeks; group 4, treated orally with CCl₄ (0.5 ml/kg) for three doses at 48 h intervals; groups 5 and 6, treated orally with the two tested doses of CMC plus CCl₄. At the end of the treatment period (day 22), the animals were kept fasting over night and sacrificed then the bone marrow and liver samples of each animal were removed for the genetic alteration and apoptotic gene expressions studies.

2.2.2. Caspase-3

Lysates were prepared by homogenizing liver tissue in 0.25 mM sucrose, 1 mM EDTA, 10 mM Tris, and a protease inhibitor cocktail. The lysates were then centrifuged at 14,000 g for 10 min at 48 °C and supernatants (50 μ g of protein) were incubated for 1 h at 37 °C in HEPES buffer containing 100 μ M concentrations of the specific fluorogenic substrates (7-amino-4-methylcoumarin N-acetyl- L-aspartyl- L-glutamyl- L-valyl-L-aspartic acid amide, Ac-DEVD-AMC). Cleavage of the caspase substrates was monitored using a spectrofluorimeter (Hitachi F-2000 fluorimeter; Hitachi LTD, Tokyo, Japan) at excitation/emission wavelengths of 380/460 nm. Activity was expressed as fluorescence units per milligram of protein per minute of incubation (UAF/min/mg protein).

2.2.3. RNA extraction and RT-PCR

Liver samples (200 mg) were quickly thawed and homogenized in 2 ml of Trizol and total RNA was isolated according to the manufacturer's directions. RNA was resuspended in RNase-free water, quantitated using UV spectrophotometer, and

stored at -80°C . The quality of the isolated RNA was assessed by measuring the absorbance at 260 nm, analyzing the A260/A280 ratio (1.7-2).

For cDNA synthesis, 3 μg of total RNA were heated to 70°C for 10 min then placed immediately on ice for 10 min. To each sample, 4 μl of 5x first strand buffer, 2 μl of 0.1 mol/l DTT, 4 AL of 2 mmol/l each deoxynucleotide triphosphate mix,

1 μl of oligo (dT) primer and 1 μl of Superscript II reverse transcriptase were added. Reverse transcription was then carried out at 42°C for 50 min, followed by heating to 70°C for 15 min and cDNA samples were stored at -20°C until assayed. cDNAs were amplified using specific primers for mouse Bcl-2 and *bax* **Table (1)**.

Table (1): Sequences of primers used for amplification

Gene	Sense and antisense	PCR product (bp)	Ref.
Bcl-2	Sense 5-TTGTGGCCTTCTTTGAGTTCG-3 antisense 5-TACTGCTTTAGTGAACCTTTT-3	332	Agarwal et al. (1999)
Bax	Sense 5-ACCAGCTCTGAGCAGATCATG-3 antisense 5-GGGATTGATCAGACACGTAAG-3	626	Zhang et al. (2006)
β -Actin	Sense 5'-CGTGACATCAAAGAGAAGCTGTGC-3', antisense 5'-CTCAGGAGGAGCAATGATCTTGAT-3'	376	Baek et al. (2007)

Gene expression was assayed according to the manufacturer's instruction. The PCR program cycles were set as follows: initial denaturing at 95°C for 20 s, followed by 40 cycles (95°C for 3 s, 60°C for 30 s). β -actin mRNA was used as an internal standard. Bcl-2 and *bax* mRNA expressions were determined by quantitative reverse transcription-PCR (RT-PCR) and normalized against β -actin mRNA levels. The PCR product was run on a 2% agarose gel in Tris-borate-EDTA buffer and visualized over a UV Trans-illuminator. The ethidium bromide-stained gel bands were scanned and the signal intensities were quantified by the computerized Gel-Pro (version 3.1 for window 3). The ratio between the levels of the target gene amplification product and the β -actin (internal control) was calculated to normalize for initial variation in sample concentration as a control for reaction efficiency (Raben *et al.*, 1996).

2.2.4. Micronucleus test:

Micronucleus assay was carried out on bone marrow according to the method described by Schmid (1975). The femurs were dissected out and the bone marrow was flushed out, vortexed and centrifuged. The pellet was resuspended in a few drops of fetal calf serum. Smears were made on pre-cleaned dry slides, air dried and fixed in absolute methanol and the slides were stained with Giemsa stain. At least 2000 erythrocytes were observed and the numbers of polychromatic erythrocytes were

counted. The micronuclei were recorded and micronuclei per 1000 cells were calculated.

2.2.5. DNA Fragmentation Assay

2.2.5.1. DNA extraction

DNA fragmentation was used as a measure of apoptotic. The presence of DNA ladder was determined according to Sambrook *et al.*, (1989) and the modifications described by Xu *et al.*, (1996). The absorbance of the DNA solution was read spectrophotometrically at absorbances of 260 and 280 nm. Equal amounts of DNA were taken after spectrophotometric analysis as described by Kamalay *et al.*, (1990).

2.2.5.2. Agarose gel electrophoresis

A gel was prepared with 2% agarose containing 0.1% ethidium bromide. The gel was electrophoresed using the submarine gel electrophoresis machine. The DNA was visualized and photographed with illumination under UV light.

2.2.6. Comet assay (Single Cell Gel Electrophoresis)

DNA damage was measured using the comet assay under alkaline conditions and dim indirect light according to the method described by Singh *et al.*, (1988) with a few modifications. Briefly, 120 μl of 0.5% normal melting point agarose in Ca^{+2} and Mg^{+2} -free phosphate buffer at 56°C were quickly layered onto a fully frosted slide and immediately covered with a cover-slip. The slides

were kept at 4°C to allow the agarose to solidify. After gently removing the cover-slip a 50 µl aliquot of cell suspensions of either bone marrow or liver were mixed with an equal volume of 1% low melting point agarose at 37°C and quickly pipetted onto the first agarose layer in the same manner. Finally, 70 µl of 0.5% LMP agarose were added to cover the cell layer. The slide sandwiched without cover-slips and were immersed in freshly prepared, cold lysing buffer (2.5 mol/l NaCl, 100 mmol/l Na₂ EDTA, 10 mmol/l Tris, 1% *N*-Lauroyl sarcosine sodium salt, pH 10, with 1% Triton X-100 added just before use) and kept at 4°C for 45 min to 1 h. The slides were placed on a horizontal gel electrophoresis platform and were covered with cold alkaline buffer (300 mmol/l NaOH, and 1 mmol/l Na₂ EDTA) for 8 to 20 min in the dark at 4°C to allow DNA unwinding and expression of the alkali-labile sites. The timing for lysis and unwinding was determined empirically for each cell line. Electrophoresis was conducted at 4°C in the dark for 20 min at 25 V and 300 mA. The slides were then rinsed gently twice with neutralizing buffer (0.4 mol/l Tris, pH 7.5). Each slide was stained with 120 µl of propidium iodide at a concentration of 5 µg/ml and covered with a cover-slip. Comet tail lengths were quantified as the distance from the centrum of the cell nucleus to the tip of the tail in pixel units, with the mean tail length being determined as the mean length of twelve tails.

2.2.7. Sister chromatid exchanges (SCE's) and chromosomal abnormalities in bone marrow:

2.2.7.1. Sister chromatid exchanges:

The method described by Allen (1982), for conducting *in vivo* SCE's induction analysis in mice was applied with some modifications. Approximately 55 mg 5'-Bromodeoxyuridine tablets were inserted in mice subcutaneously (s.c.) 21-23 hrs before sacrifice. Mice were injected intraperitoneally with colchicine at a final concentration of 3 mg/kg b.w 2 h before sacrifice. Bone-marrow cells from both femurs were collected and the fluorescence-photolysis Giemsa technique was used (Perry and Wolff, 1974). Forty well spread metaphases were analyzed per mouse to determine the frequency of SCE's/cell.

2.2.7.2. Chromosome abnormalities:

For cells preparations, animals within different groups were injected i.p. with colchicines, 2 hrs before sacrifice. Chromosome preparations from bone marrow cells were carried out according to the method described by Yosida and Amano (1965). One hundred well spread metaphases were analyzed per mouse. Metaphases with gaps, chromosome or

chromatid breakage, fragments and deletions were recorded.

2.2.8. Statistical analysis

Data were analyzed statistically by "Analysis of Variance" (ANOVA) and groups were compared by Duncan's Multiple Range Test (DMRT). *p* values ≤ 0.05 were considered as significant. The significance of the results from the control data was calculated using (t- test) for SCE's and chromosome abnormalities.

3. Results

3.1. The levels of caspase-3 activities:

The levels of caspase-3 activities showed high apoptotic rate in mice treated with CCl₄ compared to the control group. Animals treated with CMC at the two tested doses show no significant increase comparable to the control. The apoptotic rate was significantly reduced when CMC co-administrated with CCl₄. The high dose of CMC was more effective than the low dose to reduce apoptotic rate (Fig. 1) since these treatments decline the caspase-3 activities and resulted in inhibition reduced from 89.4 in CCl₄ to 65.2 in CMC1 and 54.1% in CMC2. Moreover, the activation of caspase 3 also showed a good correlation with comet tail formation.

Fig. 1 Alterations of caspase 3 activity in mice treated with CCl₄ alone or in combination with CMC

3.2. Evaluation of genes expressions

The ratio between *bax*/ β -actin indicate an over expression in *bax* compared to the ratio between control/ β -actin (Fig. 2 & 3) which increased to reach 2 in the animals treated CCl₄ while in control it was 0.87. On the other hand, the ratio of Bcl-2/ β -actin was decreased compared to control/ β -actin ratio in mice treated with CCl₄ which decreased from 1.71 to 0.91 (Fig. 2 & 4). Treatment with CMC at the low dose reduced the ratio of expression of mRNA *bax* compared with CCl₄-treated group from 2 to 1.38.

While treatment with CMC at the high dose resulted in a further reduction in the ratio expression of mRNA *bax* to reach 1.01. Moreover, treatment with CMC at the two tested doses increased the expression of mRNA *Bcl-2* ratio in a dose dependent fashion from 0.91 in CCl_4 group to reach 1.28 in the group treated with CCl_4 plus CMC at low concentration and increase the ratio to reach 1.46 in the group treated with CCl_4 plus CMC2 as shown from the results of image analysis

Fig.2. Effect of CCl_4 and CMC on expression pattern of *bax* mRNA level in liver. The 626 and 376, 332 bp fragments represent *bax* transcript, β -actin as internal standard and *Bcl-2* respectively; lane M: molecular marker (Φ x174 DNA HaeIII digest). Lane 1: control, lane 2: CMC1, lane 3: CMC2, lane 4: CCl_4 , lane 5: CMC1 + CCl_4 and lane 6: CMC2 + CCl_4 .

Fig 3. The ratio between *bax*/ β -actin in mice treated with CCl_4 alone or in combination with CMC1 and CMC2. Values represent mean \pm S.E. for each group of mice.

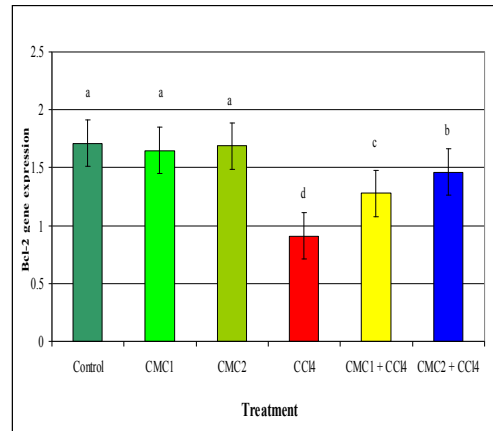

Fig 4. The ratio between *Bcl-2*/ β -actin in mice treated with CCl_4 alone or in combination with CMC1 and CMC2. Values represent mean \pm S.E. for each group of mice.

3.3. Micronucleus

The results of MnPCEs are presented in **Table (2)** and indicated that mice treated with CCl_4 alone showed a high frequency of MnPCEs compared to the control group. However, animals treated with CCl_4 and CMC at the two tested doses showed a significant reduction in the mean of MnPCEs which reached 31.2 in CCl_4 -treated group to 18.6 in CCl_4 plus CMC1 group meanwhile; the mean MnPCEs in CCl_4 plus CMC2-treated group reduced to reach 10.4. Moreover, CMC alone did not induce any significant differences in the frequency of MnPCEs compared to control group.

3.4. Percentages of DNA fragmentation in the liver tissue

The current results showed that CCl_4 induced apoptotic DNA fragmentation in mice liver on agarose gel (**Fig 5**). Animals treated with CCl_4 revealed necrosis where the DNA breakdown was random and led to irregular-length DNA fragments with an indistinct pattern on gel electrophoresis (lanes 3&4). No apoptotic bands were observed in animals given the combined treatments of CCl_4 and CMC (lanes 6 and 7). Moreover, the administration of CMC at the two doses did not induce any differences from the control group (lanes 2 & 5). On the other hand, the results of DNA fragmentation in CCl_4 -induced apoptotic changes in the liver are presented in **Table (3)** and indicated that the percentage of DNA fragmentation

Table (2): Micronucleus test and comet assay in bone marrow of mice treated with CCl₄ alone or in combination with CMC

Treatments	PCEs %	No. Mn-PCEs	Mn-PCEs Mean ± S.E.	% of cells showing comet tails	Comet tail length M ± SE
Control	52.2	21	4.2 ± 0.8 ^d	1.4	1.52 ± 0.22 ^d
CMC1	53.1	19	3.8 ± 0.66 ^d	0.8	1.06 ± 0.05 ^d
CMC2	55.4	23	4.3 ± 0.37 ^d	1.0	0.98 ± 0.04 ^d
CCl ₄	41.4	156	31.2 ± 1.77 ^a	15.0	6.9 ± 0.28 ^a
CMC1 +CCl ₄	48.0	93	18.6 ± 1.63 ^b	9.2	3.95 ± 0.2 ^b
CMC2 +CCl ₄	50.0	52	10.4 ± 1.6 ^c	6.2	2.49 ± 0.20 ^c

Five mice were used in each group. Means with different superscripts (a, b, c, d) between groups in the same column are significantly different at P<0.05.

significantly increased in the group treated with CCl₄ compared to the control group. Treatment with either CMC1 or CMC2 showed a decrease in the percentage of DNA fragmentation. However, mice treated with CCl₄ and received either CMC1 or CMC2 showed a significant improvement in the percentage of DNA fragmentation towards the control values

3.5. Comet assay

DNA damage assayed using fluorescence microscopy in individual cells in the animals treated with CCl₄ showed the comet tail which indicated that cellular DNA was fragmented due to apoptotic change. The percentages of the tailing cells calculated in each tested group for bone marrow cells and hepatocytes are presented in **Tables (2 & 3)**. It is clear that CCl₄ increased the percentage of cells with comet tail to 15% and the mean tail length to 6.9 ± 0.28 in bone marrow cells **Table (2)**. However, in hepatocytes, the percentage of cells with comet tail was increased to 23.4% and the mean tail length was also increased to 9.87 ± 0.38 in hepatocytes **Table (3)**. The percentage of cells with comet tail and the mean of tail length in the groups treated with CMC at the two tested doses were comparable to the control group. On the other hand, animals treated with CCl₄ and CMC1 showed a decrease in the percentage of cells with comet tail to 9.2% and 12.4% and the mean of tail length to 3.95 ± 0.2 and 6.54 ± 0.21 for

bone marrow and hepatocytes respectively. It is of interest to mention that a further reduction was observed in the percentage of cells with comet tail and the mean of tail length in the group treated with CCl₄ and CMC2 in both bone marrow and hepatocytes since these values recorded 6.2% for cells with comet tail and 2.49 ± 0.20 for the mean of tail length in bone marrow however; the percentage of cells with comet tail recorded 5.4% and the mean of tail length recorded 3.17 ± 0.22 in the hepatocytes.

Fig 5. Agarose gel electrophoresis of DNA extracted from liver of mice after treatment, lane M: molecular marker (Φ x174 DNA HaeIII digest), lane 1: control, lane 2: CMC1, lanes 3 & 4: CCl₄, lane 5: CMC2, lane 6: CMC2 + CCl₄ and lane 7: CMC1+CCl₄

3.6. Chromosomal aberrations and sister chromatid exchanges (SCE's) in bone marrow cells

The frequencies of SCE's/cell induced by CMC were not significantly different compared to the control group. Animals treated with CMC three weeks prior to CCl₄ showed a significant decrease in the mean percentage of SCE's/cell induced by CCl₄ alone and recorded 11.56 ± 0.44 in CCl₄-treated group and 7.1 ± 0.3 and 5.52 ± 0.24 in the groups pre-treated with CMC at the two tested doses respectively **Table (4)**. Furthermore, the percentage of inhibitory index increased from 38.58% with low dose to 52.24% with the high dose of CMC **Table (4)** and **Fig (6)**. Data presented in **Table (4)** showed the number and percentage of different

chromosomal aberrations induced in different groups. These data revealed that both the low and high doses of CMC significantly (p<0.01) reduce the percentages of aberrant cells compared to the control group in a dose dependent manner. Moreover, CMC succeeded to block the chromosomal aberrations induced by CCl₄ and the percentage of reduction reached 40.6 and 58.1% after treatment with CMC1 and CMC2 respectively

4. Discussion

In the current study, we evaluated the protective role of CMC against CCl₄-induced apoptosis and genetic alterations via the determination of caspas-3, expressions of apoptosis related genes such as bcl-2 and bax, DNA fragmentation, comet formation, sister chromatid exchanges and chromosomal aberrations in mice.

Fig. (6). Sister Chromatid exchanges in bone marrow cells of mouse treated with CCl₄ (right) or CCl₄ plus CMC (left).

The selective dose of CCl₄ and CMC were literature based (Singab et al., 2005; and Khodaghali et al., 2010). It is well documented that the toxicity of CCl₄ is thought to involve two phases; first, CCl₄ metabolism by cytochrome P450 in the hepatocytes produces the highly reactive CCl₃-radical, which leads to lipid peroxidation and membrane damage. The second step is a Kupffer cell mainly related inflammatory response. Kupffer cells are activated by free radicals and secrete cytokines that attract and activate neutrophils. Neutrophils themselves release reactive oxygen intermediates (ROIs), thereby enhancing the liver injury (Louis et al., 1998). Excess ROI, a condition referred to as oxidative stress, is considered to be a major contributor to cell injury, although many studies have shown that higher levels of ROIs can also activate specific genetic programs in various cells (Fredovich, 1978; McCord and Fredovich, 1978; Bartosz, 2009). In the current study, CCl₄ significantly increased caspase 3 activity and a pro-apoptotic gene (bax) expression as well as decreased anti-apoptotic gene (Bcl-2) gene expression. The significant high level of bax expression found in liver of CCl₄-treated mice indicated that these cells are susceptible to apoptosis. In this concern, Masson et al., (2000) reported that the proapoptotic proteins Bad and Bax were significantly higher in liver cirrhosis induced by CCl₄ and apoptosis takes place in liver during CCl₄-induced cirrhosis. The results revealed that treatment with CCl₄ resulted in a significant increase in

micronucleus (MN) formation in bone marrow cells which represents fragments of the chromosome or whole chromosomes resulting from clastogenic or aneugenic events (Savage, 1989; Fenech and Morley, 1989) since micronucleus formation is the very early steps of chromatin condensation due to apoptosis (Melntleres et al., 2001).

Apoptosis lead to DNA damage as indicated by DNA fragmentation and comet formation reported in the current study since a 39.7 % enhancement of DNA fragmentation in liver of mice treated with CCl₄ compared to the control group. Similar result were observed by Lee et al., (2010) who reported that CCl₄ induced hepatocyte DNA fragmentation and cytosolic caspase-3 and caspase-8 activity in rats. Moreover, CCl₄ induced DNA strand breaks in hepatocytes and in bone marrow cells measured by single cell gel electrophoresis through the increase in comet tail length in CCl₄-treated group compared to control group. Similar result noticed by Vanitha et al., (2007) who reported that CCl₄ induced toxicity by comet formation in rats. Moreover, CCl₄ increased chromosomal aberrations and SCE's in bone marrow which arise from DNA breaks and reversion of broken fragments at almost homologous loci after their exchange between the two sister chromatids of the same chromosome (Latt et al., 1981) and hence their formation is dependent on the S-phase of the cell cycle (Kato, 1977) or on DNA replication processes (Painter, 1980; Lasne et al., 1984). SEC's is widely used as a reliable and

sensitive indicator of chromosome (DNA) instability, since the SCE patterns can reveal general genome instability (Wilcoskey and Rynard, 1990; Kang et al., 1997). The present results demonstrated a significant elevation of SCE's/cell in CCl₄-treated mice compared to control group. The *in vivo* chromosomal aberration is one of the most important bioassays for monitoring the genotoxicity of environmental chemicals (Tucker and Preston, 1996). Previous reports indicated that CCl₄ induced SCE's and chromosomal aberrations in peripheral lymphocytes of sheep (Dianovsky and Ivikova, 2001) and bone marrow of mice (Abou Gabal et al., 2007) which clarifies that CCl₄ has the ability to induce chromosomal aberrations in bone marrow cells.

CMC is a way for conversion of COS into a water-soluble form. CMC has many unique chemical, physical and biological properties such as low toxicity, biocompatibility and good ability to form films, fibres and hydrogels (Muzzarelli, 1988; Sun et al., 2008). Consequently, it has been extensively used in many biomedical fields such as a moisture-retention agent, a bactericide, in wound dressings, as artificial bone and skin, in blood anticoagulants and as a component in the drug delivery matrices (Janvikul and Thavornnyutikarn, 2003; Liu et al., 2007).

Several molecular weight (MW) COS were tested as a dietary supplement (Gades and Stern, 2005; Kaats et al., 2006). High MW COS would be expected to inhibit the absorption of certain lipids and bile acids. However, low MW COS would be predicted to absorb such substances, but would also be expected to show increased antioxidant effects. Anraku et al., (2009) showed that the administration of low MW COS to human volunteers strongly inhibited the oxidation of human serum albumin (HSA) *in vivo*. The antioxidant properties of low MW COS are substantial, whereas high MW COS was found to be much less effective in terms of antioxidant properties (Tomida et al., 2009).

According to Xue et al., (1998) and Chiang et al., (2000), low MW chitosan can be absorbed from the intestinal tract and subsequently shows a number of additional bioactivities such as antitumor, cholesterol-lowering, immunostimulating, antidiabetic, antimicrobial, and antioxidant effects, etc., in both the systemic circulation and the intestinal tract. During these biological events, the property of particular interest for this study is the antioxidant activity of COS (Xue et al., 1998; Chiang et al., 2000). In the current study, CMC was found to improve liver injury, prevent apoptosis and protect cells from damaging effects of oxygen radicals.

Moreover, CMC did not only prevent oxidative injury in bone marrow and liver cells, but also potentially interfere with apoptosis and genotoxicity due to attenuated exogenous oxidative stress. Similar results were reported by Koo et al., (2002) who indicated that COS able to protect against apoptosis in human astrocytoma cells (CCF-STTG1) induced by serum starvation. Moreover, Liu et al., (2010) stated that COS is not only reversed the decrease of cell viability and proliferation activity, but ameliorated nuclear chromatin damage in H₂O₂-induced HUVECs.

In the present study, treatment with CMC resulted in a significant reduction in all tested parameters which increased as a results of free radicals generation produced by CCl₄ including caspase-3 activities, DNA fragmentation in liver, comet formation in liver and bone marrow, micronucleus (MnPCes), frequencies of SCE's, total chromosomal aberrations in bone marrow, over expression in bax and down expression in Bcl-2. Several reports indicated that COS enhanced the resistance to the effects of oxidative stress and increased the plasma total antioxidant radical trapping capacity (Wayner et al., 1987). Moreover, Anraku et al. (2011) reported that COS reduces the levels of pro-oxidants such as cholesterol and uremic toxins in the gastrointestinal tract, thereby inhibiting the subsequent development of oxidative stress in the systemic circulation. Thus, CMC has the potential ability to act as a protein antioxidant, since oxidative stress is an important pathogenic factor in CCl₄ toxicity. Moreover, the reducing power properties of CMC are generally associated with the presence of reductions, which have been shown to exert antioxidant action by breaking the free radicals' chain by donating a hydrogen atom (Duh et al., 1999) and/or radical scavenging mechanisms of substituting carboxymethyl group (Sun et al., 2008).

In conclusion

The current work revealed a significant correlation between caspase-3 activities and the expression of bax. Meanwhile CMC decreased caspase-3 activities and bax gene expression induced by CCl₄. This may be indicated that bax may participate in the apoptosis by regulating caspase-3 and may indicate a close relationship between these two proteins in apoptosis. On the other hand, CMC increased Bcl-2 expression and indicated that Bcl-2 may play a pivotal role in the regulation of hepatic cell apoptosis and indicated that CMC treatment substantially prevents CCl₄-induced genotoxicity and apoptosis in the bone marrow and liver of mice.

STRUCTURAL AND ULTRASTRUCTURAL ALTERATIONS IN MAMMALIAN ADRENAL CORTEX UNDER INFLUENCE OF STEROIDOGENESIS INHIBITOR DRUG**Waslat W. Elshennawy* and Hanaa R. Aboelwafa**

Department of Biology and Geology, Faculty of Education, Ain Shams University, Cairo, Egypt

dr-waslat@hotmail.com

Abstract: The risk of adverse human health effects due to endocrine-disrupting chemicals is of growing concern. In recent years, ketoconazole, an imidazole derivative has been developed and currently used in the medical fields as an anti-fungal and steroidogenesis inhibitor drug. The present study aimed to investigate the influence of ketoconazole in the structural and ultrastructural characteristics of albino rat adrenal cortex. Twenty adult male rats weighing 150-200 g. were divided into two even groups; group I were *i.p.* injected with 10mg/100g.b.wt. of ketoconazole dissolved in 1ml physiological saline solution in a daily manner at 9am for 15 days. Whereas, group II were injected with 1ml saline solution in the same manner. *Histologically*, adrenal cortex of treated rat displayed hypertrophy. Glomerulosa, fasciculata and reticularis cells were loaded with lipid droplets of variable sizes, occupying almost the cytoplasm thus displacing the nuclei eccentrically, which showed signs of pyknosis, karyorrhexis and karyolysis. *Ultrastructurally*, the three cortical zones displayed the presence of hypertrophied mitochondria filled with tightly packed tubular cristae, whereas the others having cavitation results in a complete loss of cristae, and mitochondria are identified by the remainder cristae adjacent to the inner boundaries of the limiting membrane, in addition to extensive accumulation of variable sized lipid droplets and nuclei showing pyknosis and karyolysis. In conclusion, it is noticed that the destructive impacts of ketoconazole on the adrenocortical cells reflected on their functions leading to much deficiency in their performance. So, it should be taken in consideration and great concern that this drug must be utilized under restricted precautions in the medical fields to protect the human health from its hazardous impact.

[Waslat W. Elshennawy and Hanaa R. Aboelwafa. **STRUCTURAL AND ULTRASTRUCTURAL ALTERATIONS IN MAMMALIAN ADRENAL CORTEX UNDER INFLUENCE OF STEROIDOGENESIS INHIBITOR DRUG.** Journal of American Science 2011; 7(6):1077-1086]. (ISSN: 1545-1003). <http://www.americanscience.org>.

Key words: adrenal cortex, histology, imidazole, ketoconazole, rat, steroidogenesis, ultrastructure.

1. Introduction:

The risk of adverse human health effects due to endocrine-disrupting chemicals is of growing concern. Despite that, the adrenal gland is an important organ yet it is neglectable in relation to effects of endocrine disruptors (Harvey *et al.*, 2007; Diamanti-Kandarakis *et al.*, 2009). This importance is being out from the fact that the adrenocortical zones synthesize and secrete steroid hormones, which fall into three major categories; mineralcorticoid, exemplified by aldosterone which is secreted by zona glomerulosa. Aldosterone is an important regulator of salt homeostasis and fluid balance and it is a major control unit of acid/base balance (Bielohuby *et al.*, 2007). While, zona fasciculata secretes gluco-corticoid, exemplified by cortisol, which is essential for life since it has a major role in responding to environmental stimuli; it decreases protein synthesis, thereby increasing the circulating level of amino acids; it elevates blood glucose by stimulating the enzymes involved in gluconeogenesis in the liver and it mobilizes fatty acids and glycerol from adipose cells. It has also anti-inflammatory effects (Fawcett and Jensch, 2002; Campbell, 2005). By zona reticularis, small amounts of androgens are secreted.

The two principal adrenal androgens are; androstenedione and dehydroepi-androsterone, which is far less potent than testosterone and has little physiological significance. Both hormones can serve as substrates for the conversion into testosterone and estradiol (Fawcett and Jensch, 2002; Keegan and Hammer, 2002). The hormone secretions of the adrenal cortex is dependent on steroidogenic cytochrome P450 (CYP) enzymes which possibly can be the target of endocrine-disrupting chemicals affecting them (Ohlsson *et al.*, 2010).

One of the groups that effects CYPs is the imidazoles, which are medically used as antifungal treatment. Of the imidazoles in current clinical use, ketoconazole which is a broad-spectrum anti-fungal and steroid hormones biosynthesis inhibitor drug (Marty *et al.*, 2001; Schimmer and Parcker, 2006). It has great activity against a variety of yeast, dimorphic fungal, fungal infections of the gastrointestinal tract, dermatophytic infections of the skin and has been widely used in immunocompromised patients such as those with AIDS or those on chemotherapy (Vertzoni *et al.*, 2006). Also, it has anti-inflammatory activity, it may prevent the development of acute respiratory distress syndrome

and acute lung injury in critically ill patients (Wiedemann *et al.*, 2000).

Ketoconazole is an effective inhibitor of adrenal and gonadal steroidogenesis, primarily because of its inhibition of the activity of CYP17. At even higher doses, it also inhibits CYP11A1, effectively blocking steroidogenesis in all primary steroidogenic tissues (Cohen *et al.*, 2000; Schimmer and Parcker, 2006).

In the field of medicine, the great ability of ketoconazole to inhibit mineralocorticoid synthesis is used for palliative treatment of primary hyperaldosteronism (Lionakis *et al.*, 2008). Also, in a treatment strategy of resistant and hyper-cortisolemic depressive patients as an inhibitor of glucocorticoid synthesis (Brown *et al.*, 2001; Dvorak, 2011). As well as, in treatment of ACTH-secreting adenomas, palliative treatment of Cushing disease, adrenal tumors, adrenocortical carcinoma and ectopic corticotrophin production by small-cell lung carcinoma or carcinoid tumors (Gordon, 2007; Lionakis *et al.*, 2008).

Ketoconazole as inhibitor of androgen has been used for treatment of prostate cancer with promising results (Peehl *et al.*, 2001; Kinobe *et al.*, 2006; Liebertz and Fox, 2006).

Also, physicians use high-dose ketoconazole in women with advanced breast cancer resistant to conventional chemotherapy and for ovarian hyperandrogenism syndrome, including polycystic ovarian syndrome and hyperthecosis with considerable improvement in acne, hirsutism, and amenorrhea (Lionakis *et al.*, 2008).

In experimental animals, impact of ketoconazole has been studied in some biological aspects on different body organs rather than the adrenal gland (Rodriguez and Buckholz, 2003; Braddock, 2003; Amin and Hamza, 2005; Furukawa *et al.*, 2008).

It is clearly noticed from the previous literature, that ketoconazole has been widely utilized in the medical fields for the treatment of different types of diseases. But, unfortunately there is no attention for the influence of its administration on the adrenal cortex which is responsible for synthesis and secretion of different steroid hormones. Thus, the present study aimed to throw light on the influence of ketoconazole on adrenal cortical tissues from the histological and ultrastructural point of view

2. Materials and Methods:

2.1. Experimental animals

Twenty male Swiss albino rats (*Rattus norvegicus*) ranging in weight from 150-200g., acquired from Schistosoma Biological Supply Program (SBSP) Theodor Bilharz Research Institute,

were housed in clear plastic cages (2 animals/cage) with wood chips as bedding and given pellet rodent diet, in addition of milk and water *ad-libitum*. They were kept under controlled environmental conditions, including a temperature of 25°C and a 12-h light/darkness cycle.

2.2. Drug used

Ketoconazole is a synthetic imidazole of oral broad-spectrum antifungal agent (Vertzoni *et al.*, 2006; Dantas *et al.*, 2010). It is sold under trade name; Nizoral® as a tablet of 200 mg Ketoconazole which is manufactured by JANSSEN-CILAG Pharmaceutica N.V., Turnhoutseweg 30, B-2340 Beerse, Belgium.

2.3. Experimental design

The rats were randomly divided into two even groups; group I, were *i.p.* injected with 10mg/100g.b.wt. of *ketoconazole* dissolved in 1 ml of physiological saline solution in a daily manner for 15 days. Whereas, group II was kept as a control group and were injected with 1ml of physiological saline solution in the same manner.

This selected dose of ketoconazole and the route of administration have been previously used in different researches (O'Connor *et al.*, 2002; Amin and Hamza, 2005; Amin, 2008).

2.4. Histological preparations

The excised adrenal glands were fixed in Bouin's fluid for 24 hours, then subjected to the normal procedures for paraffin sectioning. Sections, of 4-6 µm were stained with haematoxylin & Eosin, dehydrated, cleared in xylene and mounted in DPX. The stained sections were examined and photographed by light microscopy (BX-40 Olympus), fitted with 4x - 40x objective lenses with an adjustable numerical aperture (3.3). Images were captured using camera (Panasonic CD-220).

2.5. Ultrastructural preparations

For ultrastructural evaluation by transmission electron microscopy as described previously by Dykstra *et al.* (2002), freshly excised adrenal glands were cut into small blocks (1×1mm³), fixed directly in cold 4F1G (i.e. 4% formalin + 1% glutaraldehyde adjusted at pH 2.2) for 24 hours, then were post fixed in 1% osmium tetroxide in 0.1M phosphate buffer (pH 7.3), dehydrated in an ethanolic series culminating in 100% acetone, and infiltrated with epoxide resin. After polymerization overnight at 60°C, semithin sections (0.5 µm) were stained with 1% toluidine blue in 1% sodium borate and examined with light microscope. Areas of cortical cells were selected and the blocks trimmed accordingly. Ultrathin sections (80-90 nm) were cut, mounted on

200 mesh copper grids, and stained with uranyl acetate and lead citrate. The stained grids were examined and photographed by JEOL.JEM-1400-EX-ELECTRON MICROSCOPE at the Central Laboratory of Faculty of Science, Ain Shams University. The photographs were printed on KODABROMIDE F5s GLOSSY Black and White-Schwarzweib- Kodak.

3. Results:

3.1. Histological studies (Haematoxylin and eosin preparations)

3.1.1. Control adrenal cortex

Figure (1) showing the three zones of adrenal cortex; zona glomerulosa, fasciculata and reticularis, respectively. As shown in figure (2), the adrenal gland is surrounded by a fibrous connective tissue capsule. Zona glomerulosa is formed of columnar or rather pyramidal cells arranged in glomeruli-like structure, which are separated by delicate trabeculae extending from the capsule. Its cells contain acidophilic cytoplasm with fairly large rounded to oval basophilic nuclei having distinct nucleoli (Fig. 2).

Zona fasciculata is composed of polyhedral or columnar cells arranged in one or two cell thick in long radial cords or fasciculae and they are separated by narrowed blood capillaries lined with endothelial cells. The cells have granulated eosinophilic cytoplasm embodying spherical basophilic nuclei showing distinct nucleoli. Binucleate cells are seen frequently (Fig. 3).

Zona reticularis is characterized by an irregular anastomosing network of intermingled cords separated by numerous wide blood sinusoids lined with endothelial cells. The cells of these cords are columnar cells having moderately eosinophilic cytoplasm, containing certain discrete granules and have rounded basophilic nuclei possessing centrally located nucleoli (Fig. 4).

3.1.2. Ketoconazole-treated adrenal cortex

Generally, the adrenal gland showed enlargement in size with its outer cortex showing hypertrophy as seen in figure (5). The fibrous connective tissue capsule being thickened with increased fibrous elements (Fig. 6).

Glomerulosa, fasciculata and reticularis cells exhibiting hypertrophy with accumulated variable sized lipid droplets in their cytoplasm. Some of these lipid droplets fused together and occupied almost the entire cytoplasm, thus displacing the nuclei eccentrically which showing clear signs of pyknosis, karyorrhexis and karyolysis as clearly observed in figures (6-8).

3.2. Ultrastructural Studies

3.2.1. Control adrenal cortex

Fine structure of zona glomerulosa cells reveal different mitochondrial configuration varying from oval to spherical shapes with a specific tubulo-saccular cristae. In addition, a fair amount of smooth endoplasmic reticulum, small Golgi vesicles and abundant number of lipid droplets are evident. The nuclei of these cells are rounded or oval in shape; sometimes wavy in appearance ensheathed by double nuclear envelopes and possessing nucleoli, peripheral dense heterochromatin and homogenous euchromatin material (Figs. 9-11).

Figures (12-14) exhibit the fine characteristic features of fasciculata cells including; abundance of rounded mitochondria with obvious tubular cristae, smooth endoplasmic reticulum in the form of branching tubules, scanty rough endoplasmic reticulum, fair amount of lysosomes and richness of lipid droplets. The nuclei are large, rounded, possessing prominent nucleoli, dense peripheral heterochromatin, lightly stained euchromatin and surrounded by double nuclear membranes. Blood capillaries lined with endothelial cells are noticed between these fasciculata cells (Fig. 12).

Zona reticularis cells are distinguished by their richness of rounded mitochondria with intensely tubular cristae, smooth endoplasmic reticulum, lysosomes and lipid droplets with varying sizes. Their nuclei are spherical or ovoid in shape contained condensed heterochromatin, euchromatin and prominent nucleoli (Figs. 15-17). Widened and clear blood sinusoids lined with endothelial cells are manifested in figure (15).

3.2.2. Ketoconazole- treated adrenal cortex

Marked ultrastructural changes of zona glomerulosa cells are illustrated in figures (18-20); their cytoplasm contain hypertrophied mitochondria with more electron dense matrices and some of them possessing small vacuolar degenerations, in addition to lysosomes and lipid droplets of variable sizes. The nuclei being electron dense, showing shrinkage, and signs of pyknosis. They are surrounded by irregular nuclear envelopes and containing electron dense nucleoli, heterochromatin and euchromatin.

Zona fasciculata cells showing hypertrophied mitochondria filled with tightly packed tubular cristae, some of them having cavitation and finally these mitochondria are identified only by the remainder cristae adjacent to the inner boundaries of the limiting membrane. Extensive accumulation of various sized lipid droplets, some of them became so large thus occupying almost the entire cytoplasm, masking the organelles and distending the cells. Fair amounts of lysosomes are seen, beside, the nuclei which displayed signs of pyknosis and karyolysis. Some

blood cells are shown in between fasciculata cells (Figs. 21-23).

Similarly, zona reticularis cells having hypertrophied mitochondria with some of them showing ruptured mitochondrial membrane, degenerated cristae and cavitation, in addition to accumulated lipid droplets of different sizes, and pyknotic nuclei surrounded by irregular nuclear membrane and containing electron dense heterochromatin and euchromatin. As well as, blood sinusoids containing stagnant blood cells are observed (Figs. 24-26).

It is worthy to mention that smooth endoplasmic reticulum, was scanty, sometimes almost absent in all examined cells of the adrenocortical zones, suggesting that it may be disintegrated under the influence of ketoconazole.

An interesting observation is seen in the resulted electron micrographs, that there are dense particles participated all over the cells of these three zones, which may have occurred as a result of a chemical reaction between ketoconazole and the chemical components of the cells.

4. Discussion

There is increasing evidence that various chemicals introduced into the environment have the potential to disrupt the endocrine system in humans and wildlife. Increasingly, the enzymes involved in the steroid biosynthesis pathway are being recognized as important targets for the actions of the endocrine-disrupting chemicals. Steroidogenic enzymes are responsible for the biosynthesis from cholesterol of various steroid hormones including glucocorticoids, mineralcorticoids, androgens, and estrogens. They consist of several specific cytochrome P450 enzymes (CYPs), hydroxysteroid dehydrogenases (HSDs), and steroid reductases (Sanderson, 2006).

In recent years, a number of imidazole derivatives have been developed and used as an anti-

fungal agents. Ketoconazole is one of the imidazole derivatives currently used in the clinical fields. It is an effective inhibitor of adrenal and gonadal steroidogenesis (Schimmer and Parker, 2006). For this property, it has been used for the treatment of different types of diseases including; Cushing disease, hyper-cortisolemic depressive patients, adrenal tumors, adrenocortical carcinoma, adrenal adenomas, prostate cancer, advanced breast cancer and various cancer cell lines such as hepatic metastasis and pulmonary metastasis (Lionakis *et al.*, 2008).

The majority of severe degenerative changes induced in the adrenal gland following pathological disorders are often judged by the physiological tools. Steroidogenesis inhibition of ketoconazole has also been studied in experimental animals by O'Connor

et al., (2002), which evaluated a 15-days screening assay using intact male rats for identifying physiologically steroid biosynthesis inhibition of ketoconazole, also Shin *et al.* (2006) elucidated a 28-days repeated dose toxicity study of ketoconazole in rats. These authors reported in their interesting researches that ketoconazole caused increase of adrenal's weights, reflecting on the level of these hormones; decrease of testosterone, increase of estradiol, luteinizing hormone (LH) and follicular stimulating hormone (FSH). They suggested that ketoconazole should be identified as an impairment of endocrine-related compound.

The adrenal gland is the most important steroidogenic tissue in the human body and essential for survival. All steroidogenic processes take place in the adrenal cortex (Bielohuby *et al.*, 2007). The adrenal cortex, and in particular zona fasciculata has been reported by Rosol *et al.* (2001) to be among the most common site lesions in the endocrine system. The factors which predispose this organ to such lesions include: its disproportionately large blood supply per unit mass; its high content of lipids and the susceptibility of its unsaturated fatty acids to peroxidation damage; and its high levels of cytochrome P450 which metabolize xenobiotics to reactive intermediates. In addition, the adrenal expresses several of the pathways for steroid production present in the testes and ovaries. Therefore, toxic chemicals can affect the adrenal or its axis directly or indirectly in a manner similar to the testes and ovaries.

The present study throws the light on the impact of ketoconazole on adrenal cortex from the histological and ultrastructural point of view, because these types of studies did not receive marked attention in spite of its importance to characterize lesions that may suppress the function of the adrenocortical cells.

In the present investigation, ketoconazole is found to have destructive structural and ultrastructural alterations in rat adrenal cortex. The most striking change is the enlargement and extensive accumulation of lipid droplets throughout the cytoplasm of the three zones cells. This alteration was also reported in the influence of chronic treatment with aminoglutethimide, an inhibitor of the cholesterol enzyme P450_{scc} (Szabo *et al.*, 1996), congenital lipoid adrenal hyperplasia in humans and mice, a disorder caused by hereditary deficiency of the StAR protein (Miller and Strauss, 1999), hormone-sensitive lipase (HSL) deficiency in mice (Li *et al.*, 2002) and after chemotherapy administration (Hermenean *et al.*, 2008).

In this work, distinct alterations are evidenced in the mitochondria displayed by hypertrophy with

degeneration of the cristae resulting in cavitation of their matrix. These lesions are not reported previously in rat adrenal cortex. In our opinion this hypertrophy and cavitations in mitochondria probably resulted from inhibition of the conversion of cholesterol to pregnenolone, cholesterol may accumulate within the mitochondria. Consequently, it undergo considerable hypertrophy and vacuolation. Also, similar results were observed by Ishihara *et al.* (1974) in human adrenal cortex in Cushing's syndrome. They explained that the intra-mitochondrial vacuoles might be associated with the deposition of steroids or their related compounds in the cristae.

The profound lesions observed in mitochondria and smooth endoplasmic reticulum might be sufficient to cause impairment of steroid synthesis in accordance with Guerrero *et al.* (2010), who reported that these organelles play a great role in steroidogenesis within the cortex, though, they involve in the coordinated actions of cytochrome P450 and the enzyme 3-hydroxysteroid dehydrogenase (3 HSD), which are distributed between the mitochondria and the smooth endoplasmic reticulum. The rate-limiting step in steroid hormone biosynthesis is the translocation of substrate cholesterol from the outer mitochondrial membrane to cholesterol side-chain cleavage enzyme (CYP11A), the first enzyme in the steroidogenic pathway, which is located inside the mitochondria as Rainey *et al.* (2004) and Isola *et al.* (2010) elucidated in their interesting studies.

It is well known that, adrenocortical cells require constant supply of cholesterol as a precursor for the conversion of steroid hormones. Cholesterol delivery in the adrenal glands involves three major processes: uptake of lipoprotein-derived cholesterol via low density lipoprotein receptor (LDLR) mediated endocytic pathways and scavenger receptor class B member 1 (SCARB1)-mediated "selective" uptake pathways; endogenous cholesterol biosynthesis in endoplasmic reticulum; and cholesterol mobilization from intracellular cholesterol esters (CEs) stored in lipid droplets (Kraemer, 2007). The delivered CEs should be hydrolyzed to be utilized for steroidogenesis by non-lysosomal neutral lipases. Therefore, CE hydrolysis plays a pivotal role not only in the break down of stored lipids but also in the lipoprotein uptake and utilization. The resultant unesterified cholesterol is transported to mitochondria by the steroidogenic acute regulatory protein (StAR), where it is converted into the different steroid hormones by a battery of oxidative enzymes (Miller, 2007).

Ketoconazole was found to inhibit cholesterol synthesis in a dose-dependent fashion by blocking

conversion of lanosterol to cholesterol. Other lipid-modifying properties of ketoconazole include decreasing of lipoprotein lipase and 3-hydroxy-3-methylglutaryl coenzyme A reductase activities, inhibition of intestinal cholesterol absorption and bile acid synthesis, and upregulation of LDL-C receptor activity (Lionakis *et al.*, 2008).

Ultimately, It seems, that the impaired steroidogenesis is an important mechanism of toxicity in the adrenal cortex. It may have occurred due to disruption of cytochrome P450 enzymes, accordingly the cholesterol biosynthesis will be suppressed. This will lead to the accumulation of lipid droplets that seen in the electron micrographs, indicating that the target organ of ketoconazole on adrenocortical cells are mitochondria since the treated animals had destructive mitochondria on which cytochrome P450 enzymes are enclosed.

In conclusion, it is noticed now that the destructive impacts of ketoconazole on the adrenocortical cells reflected on their functions leading to much deficiency in their performance. So, it should be taken in consideration and great concern that this drug must be utilized under restricted precautions in the medical fields to protect the human health from its hazardous impact.

Cytopathic effect of coccoid forms of *Helicobacter pylori* in Albino rats and Swiss mice**Rajaa M. Milyani**

Department of Biological Sciences, Faculty of Science, King Abdulaziz University.

*Corresponding author: helicobacter2011@hotmail.com

ABSTRACT: The effect of coccoid forms of a vaculating cytotoxin A positive *Helicobacter pylori* strain on *Mus musculus* (Swiss mice) and *Rattus norvegicus* (Albino rats) was studied. Two groups of Swiss mice and Albino rats were used. The first group of mice and rats was orally inoculated with coccoid forms of *Helicobacter pylori*, whereas, the second group of mice and rats were untreated and used as a control. The animals that had been orally inoculated with a total count of 7.0×10^5 bacterial cell / ml died after 5-7 days of inoculation (mice), whereas, rats died after 7-9 days. Symptoms of mouth ulcers, darkening of the ventral part and peripheries and loss of weight were apparent, in addition to slow movement and general weakness compared to the control group. Histological examination of the stomach of the inoculated animals showed marked degeneration of the epithelial lining membrane and dark dense bodies - most probably - coccoid forms inside gastric glands. In addition dilated blood vessel, degenerated, vacuolated fused cells with coccoid forms and intravascular haemolysis were observed. These findings may indicate the toxicity of coccoid forms of *Helicobacter pylori* and hence their possible pathogenic role in humans.

[Rajaa M. Milyani. Cytopathic effect of coccoid forms of *Helicobacter pylori* in Albino rats and Swiss mice. Journal of American Science 2011; 7(6):1087-1092]. (ISSN: 1545-1003). <http://www.americanscience.org>.

Key words: *Helicobacter pylori*, Albino rats, Swiss mice, coccoid forms, toxicity, cytopathic effect.

1. Introduction:

Helicobacter pylori (*H. pylori*) is a microaerophilic, Gram negative, motile bacterium that is known to exist in two morphological forms: the helical and the coccoid form. It has been reported that spiral forms may transform to the coccoid shape after two hours of exposure to oxygen (Borriello, *et al.* 2005). However, other researchers found that it converts into the coccoid form when it is exposed to detrimental environmental conditions (Andersen and Wadstrom, 2001; Nilsson, *et al.* 2002). The role of *H. pylori* spiral forms in many types of gastritis, gastric and duodenal ulcers, gastric carcinoma and MALT lymphoma have been documented (Uemura, *et al.* 2001; Blaser and Atherton, (2004). Furthermore, its implication in the development of cardiovascular, dermatological diseases and lately in the development of Parkinson's disease has been suggested, Wedi and Kapp (2002); Aceti, *et al.* (2004). Hernando-Harder, *et al.* (2009); Testerman, *et al.*, (2011). Above all, Scientists estimated that more than 50% of the world's population harbor *H. pylori* in their stomach, Talarico, *et al.*, (2009) that can persist for life.

Interestingly, what makes infection of this bacterium a complicated dilemma, is that treatment with antibiotics induces the transformation of some spiral forms into the coccoid forms which consequently leads to failure of treatment, Kusters, *et al.*, (1997); Brenciaglia, *et al.* (2000).

Although many authorities in the field used to believe that coccoid forms are manifestation of bacterial cell death, Kusters, *et al.*, (1997), yet many recent researchers started to prove the opposite of this concept, Mizoguchi, *et al.* (1999); Azevedo, *et al.*, (2007). In fact, different reports recorded the ability of coccoid forms to cause gastritis in experimental mice and to convert in-vivo into the spiral form Wang, *et al.*, (1997); She, *et al.*, (2003). Moreover, documented research proved that coccoid forms coexist with spiral forms in the stomach, and by semi-quantitative analysis the number of coccoid forms was found to be significantly greater in adenocarcinoma than that in benign peptic ulcers and were observed in more severely damaged regions of the gastric mucosa, Chan, *et al.*, (1994); Saito, *et al.*, (2003). The fact that –so far- coccoid forms are said to be unculturable, Azevedo, *et al.*, (2007), does not exclude their ability to cause disease or in transmitting infection, since an increasing number of studies support the potential role of coccoid forms in *H. pylori* diseases, Figueroa, *et al.*, (2002).

The aim of the present study was to investigate the ability of *H. pylori* coccoid forms to cause pathological changes in laboratory animals and hence their possible role in the transmission of infection.

2. Materials and Methods:

2.1. Materials:

2.1.1. Bacterial strain:

H. pylori was isolated from a gastric biopsy of a patient complaining of chronic superficial gastritis, the clinical specimen was provided by the Gastroenterology department at King Khalid National Guard Hospital, Jeddah City, Saudi Arabia.

2.1.2. Laboratory animals:

20 healthy male *Mus musculus* strain MF1 (Swiss mice) and 20 healthy male *Rattus norvegicus* (Albino rats) aged three months and weighing 33-35 g and 230-250 g respectively were obtained from King Fahad research centre, King Abdul Aziz University (KAU). Each group of both mice and rats was divided into three subgroups: the first contained 5 inoculated animals with 1 ml of 7.0×10^6 Bacterial cell /ml, the second contained 10 inoculated animals with 1 ml of 7.0×10^5 Bacterial cell /ml and the third was five untreated animals as a control. The mentioned inoculum (infectious dose) was given as one dose/ day.

Each animal was housed in a separate stainless steel cage containing soft wood chips. A basal diet composed of 60% ground corn meal, 15% ground beans, 10% wheat bran, 10% corn oil, 30% casein, and 1% minerals mixture was given. Water was supplied daily. Ghanem, and Aly, (2003). Animals were kept at 21°C air-conditioned room.

2.1.3. Oral inoculation of animals:

The treated animals (15 mice and 15 rats) were mildly anaesthetized –only before inoculation - using chloroform saturated cotton which was placed in the middle of each cage. For daily inoculation, the mouse or rat was held firmly by the scruff of the neck in a vertical position (Lee and Megraud, 1996) and orally inoculated using a disposable sterile 1 ml syringe (JMC, Korea) for five days (mice) and seven days (rats). The control group of animals was untreated.

2.2. Methods:

2.2.1. Culture and Identification:

Gastric biopsy was cultured on Blood and Chocolate agar using the rubbing technique and the plates were incubated under microaerophilic conditions at 37°C for five days (Milyani and Barhameen, 2004). Identification was by morphological studies, urease, catalase and oxidase tests in addition to motility (Lee and Megraud, 1996). The colonies were subcultured on five blood agar plates and after five days incubation, the harvested colonies from each plate were transferred to a separate Cryovile filled with 0.5 ml Thioglycolate broth with 15% glucose (five Cryovile), and stored at - 20°C as stock culture for further studies. Five years later, a 10

µl diameter sterile disposable loop (Sara Med. Saudi Arabia) was dipped in the stock culture and a loopfull was streaked on both Blood and Chocolate agar and incubated under the appropriate conditions as mentioned above.

Molecular identification for the isolated strain, using 16S rRNA and VacA genes, was carried out by Professor Osama El Sayed (National Research Centre, Cairo, Egypt).

2.1.2. Preparation of the inoculums:

Two inocula were prepared from the stock culture (a total count of 7.0×10^6 and 7.0×10^5 Bacterial cell /ml) by using counting chamber; in addition, a drop of each inoculum was examined by phase contrast microscope.

2.1.3. Preparation of histological sections:

Treated and untreated mice and rats were dissected and the stomach was removed and preserved in Boin's solution for histological studies. Cross sections were done and stained with haematoxylin and eosin dyes as described by Lee and Megraud, 1996 at King Fahad research centre (KAU).

3. Results:

3.1. Culture and Identification:

Culture of gastric biopsy revealed typical morphology of *H. pylori* colonies, proven by positive urease, catalase and oxidase tests. Gram stain also showed Gram negative S-shaped bacteria, in addition, using phase contrast microscope, the well recognized motility of *H. pylori* was recorded. However, culturing from the stock culture after five years gave undetectable viable counts, though, examining drops of both inocula using phase contrast microscope showed complete conversion to coccoid forms some of which appeared motile.

3.2. Identification of 16S rRNA gene and VacA gene:

PCR amplifications of the *H. pylori* isolate revealed the fragments with expected sizes of 163 bp that represented the 16S rRNA gene and 750 bp that represented the VacA gene.

3.3. Laboratory animals:

The animals in the preliminary study that were orally inoculated with 7.0×10^6 bacterial cell/ml, died after 24 hours. On the other hand, both orally inoculated mice and rats with 7.0×10^5 *H. pylori* cell/ml, showed different abnormalities and pathological manifestations. Symptoms started to appear from the third day of inoculation as ulcers around the mouth, general weakness with slow movement, loss of appetite, darkening of the ventral part and terminals with some atrophy and loss of weight (fig. 1 and fig. 2).

The group of mice died after 5-7 days whereas, the group of rats died after 7-9 days, and the final average weight was decreased to 17.2 g for mice and 215 g for rats. No pathological changes were obtained in the control group that only drank sterile tap water.

Fig.1 Albino rat after oral ingestion with coccoid forms of *Helicobacter pylori* showing ulcer of the mouth and dark atrophied terminals.

Fig.2 Swiss mouse after oral ingestion with coccoid forms of *Helicobacter pylori* showing ulcer of the mouth, dark ventral part and atrophied terminals.

3.4. Histological sections:

Figures 3 – 5 show different Sections of mucosal layer of Albino rat's stomach that were orally inoculated with *H. pylori* coccoid forms. Degeneration of the epithelial lining membrane and dark dense bodies- most probably- coccoid forms inside gastric glands were apparent in fig. 3 (A) compared to the normal section of control rat fig. 3 (B). In addition fig. 4 (A) shows degeneration of epithelial lining membrane with no goblet cells and many vacuolated cells, while fig. (B) shows dilated blood vessel, degenerated, vacuolated fused cells with dark dense bodies. Moreover, in Fig. 5, intravascular haemolysis was seen.

On the other hand, figures 6 -7- show different Sections of mucosal layer of Swiss mice stomach that were orally inoculated with *H. pylori* coccoid forms in which fig. 6 shows highly damaged epithelial lining membrane with degenerated cells in the inner layers and many scattered dark dense bodies (coccoid forms), in contrast to fig. 6 (B) which shows normal stomach mouse wall. However, many coccoid forms in the mucosa and sub mucosa and connective tissue were seen in Fig. 7 (A) whereas, wavy fibres in the submucosal layer on which many dark bodies were deposited.

Fig.3 Section of mucosal layer of Albino Rat stomach (A) orally inoculated with *H. pylori* coccoid forms showing degeneration of the epithelial lining membrane and dark dense bodies inside gastric glands (B) normal section of control (x 400).

Fig.4 Section of mucosal layer of Albino Rat stomach that had been orally inoculated with *H. pylori* coccoid forms (A) showing degenerated epithelial lining membrane with no goblet cells and many vacuolated cells (B) showing dilated blood vessel (black arrow) and degenerated, vacuolated fused cells with dark dense bodies (x 400).

Fig.5 Section of Albino Rat stomach that had been orally inoculated with *H. pylori* coccoid forms showing intravascular haemolysis (x 400).

Fig.6 Section of mouse stomach that had been orally inoculated with *H. pylori* coccoid forms showing highly damaged epithelial lining membrane with degenerated cells in the inner layers and many scattered dark dense bodies (A), (x 630).
Section (B) show normal stomach mouse wall (x 250)

Fig.7 Section of stomach wall of Swiss mouse (A) shows many dark dense bodies in the mucosa, submucosa and connective tissue (x 260). (B) Section in the wall of mouse stomach showing many wavy fibers in the submucosal layer plus many dark dense bodies deposited on the fibers (x 630).

4. Discussion

Coccoid forms of *H. pylori* have for a long time been a debate between scholars. The fact that no one should ignore and has been documented is their existence in the stomach of patients together with spiral forms and their possible role in pathogenicity, Saito, *et al.*, (2003). Furthermore, what makes coccoid forms a dilemma to physicians, pharmacologists and scientists is that up to date, they are said to be

unculturable, Borriello, *et al.* (2005) and after eradication therapy a small amount of them revert to the unculturable state and remain in the form of coccoids, Bardakhch'ian, (2003). Above all, *H. pylori* has been classified as type 1 carcinogen of gastric cancer by the WHO (Correa and Houghton, 2007). All the previous data was a strong stimulus for the present study which was to investigate the capability of coccoid forms to cause cytopathic effect in laboratory animals.

Wang *et al.*, (1997) demonstrated that both forms of *H. pylori* can infect mice with an inoculum size of 10^8 CFU whereas, at the present study, an infectious dose of 7×10^6 and 7×10^5 of coccoid cell /ml were used. The former only allowed 24 hours survival of both rats and mice, whereas, the latter (7×10^5) allowed survival of the tested animals for 5 – 9 days. It was surprising that although Wang and his colleagues used a higher infectious dose, yet their mice survived for a longer period. This could be attributed to the genotype of the *H. pylori* strain under study that might have been more virulent than Wang's strain and also than the strains used by She and colleagues, Wang *et al.*, (2001); She, *et al.*, (2003). The present studied strain revealed to be VacA positive which could have exerted a toxic lethal effect on the inoculated animals. In addition, observation of a drop of the stock culture by phase contrast microscope showed some motile coccoid forms indicating its viability. What's more, Milyani and Barhameen, (2003) studied the survival ability of seven *H. pylori* isolates in three different fluids aerobically, at room temperature and at 4° C and reported differences among the survival ability of the strains, since only one strain was able to maintain a detectable level of 3.88×10^4 CFU after eight days in tap water at 4° C, after which viable count completely dropped. They concluded the possibility of *H. pylori* to stay viable but unculturable and thus might be a risk for transmitting infection. Also, the high diversity and variations among *H. pylori* strains and the role of VacA in causing epithelial cell damage with formation of large vacuoles within the cells have been well established, and could be another factor for the obvious toxicity at the present work, Milyani (2011); Argent *et al.* (2008). On the other hand, the obtained results at the present work, when inoculation with sub lethal dose lead to different abnormalities and pathological manifestations such as mouth ulcers, atrophy of terminals and the apparent acute toxicity that ended by death, may prove the pathogenicity of coccoid forms to rats and mice. Moreover, the histological abnormalities that occurred in the stomach including marked degeneration of the epithelial lining

membrane and vacuolated fused cells with dark dense bodies which are most probably coccoid forms (Lee and Megraud, 1996) may indicate their potent detrimental effect and a risk factor for other pathological manifestations (Blaser and Atherton, (2004), Hernando-Harder *et al.* (2009), Testerman *et al.*, 2011). Nonetheless, we should bear in mind the immune response of the tested animals sine it could also play a role in the final outcome of infection Benaissa, *et al.* (1996); Zhao, *et al.*, (2007). Adhesion of coccoid forms to gastric mucosal cells and their role in gastro-duodenal disease has also been studied and recorded ,Liu, *et al.*, (2006); Vijayakumari, *et al.*, (1995).

In conclusion, the previous data strongly emphasize the pathogenic role of coccoid forms and recommend pursuing detailed research on this amazing phase of *H. pylori*. The clearly perceptible achievement and outcome of such research is: successful therapy, accurate diagnosis, extra biological data and the discovery of the source and precise mode of transmission which eventually will enable us to control and prevent different serious diseases caused by *H. pylori*.

Acknowledgments:

I am grateful to Dr. Ferial M. Stietieh Associate Professor of Histology, KAU, for interpretation of the histological work. My thanks are also due to Dr. Rihab Fairag, Pathologist at King Fahad Armed Forces Hospital for her help.

Protective effect of ginger (*Zingiber officinale*) against metalaxyl induced hepatotoxicity in albino mice**Hawazen A. Lamfon**

Department of Biology, Faculty of Applied Sciences, Umm Al-Qura University, Saudi Arabia.

hlfamfon@yahoo.com

Abstract: The present work studied the effect of metalaxyl, an acylalanine fungicide, on the liver of albino mice and the possible role played by the aqueous extract of Ginger (*Zingiber officinale*) in attenuating the hepatotoxicity of metalaxyl. Metalaxyl treatment induced many histological changes in the liver including congestion of blood vessels, cytoplasmic vacuolization of the hepatocytes, necrosis and fatty degeneration. Metalaxyl caused marked elevation in serum ALT and AST. It also caused an increase in malondialdehyde and depletion of the activity of the antioxidant enzymes, catalase and superoxide dismutase in the liver. Treating animals with metalaxyl and ginger extract led to an improvement in both the histological and biochemical alterations induced by metalaxyl. Moreover, ginger reduced the level of malondialdehyde and increased the activity of antioxidant enzymes, SOD and CAT. These results indicated that ginger has protective effect against liver damage induced by metalaxyl and this may be attributed to its antioxidant and free radicals scavenging properties.

[Hawazen A. Lamfon. **Protective effect of ginger (*Zingiber officinale*) against metalaxyl induced hepatotoxicity in albino mice.** Journal of American Science, 2011;7(6):1093-1100]. (ISSN:1545-0740). <http://www.americanscience.org>

Keywords: Protective effect; ginger (*Zingiber officinale*); metalaxyl; hepatotoxicity; albino mice

1. Introduction

The environmental contamination of pesticides as a result of their extensive use has become a serious problem. This stimulated the scientists to study its biological effects. Metalaxyl is a benzenoid fungicide used to control soil-borne fungal diseases on fruits, cotton, soybean, peanuts, ornamental and grasses (Sukul and Spiteller, 2000). On the other hand, metalaxyl showed hazardous effects in mammalian animals. Hrelia et al. (1996) reported that metalaxyl has cytogenetic effects on human and animal chromosomes only *in vitro* and not *in vivo*. In a long-term feeding study with mice at low levels of exposure, the animals' livers were the primary target for metalaxyl-related effect (Walker and Keith, 1992). Paolini et al. (1996) indicated the cocarcinogenic potential of metalaxyl in Swiss albino mice. Metalaxyl caused dose-dependent bradycardia, and at higher doses (250 and 300 mg/kg body weight) the sustained bradycardia led to cardiac arrest (Naidu and Radhakrishnamurthy, 1988). Sakr and Lamfon (2005) reported that metalaxyl induced histological and biochemical alterations in the liver of albino mice. Demisia et al. (2007) found that imidacloprid and metalaxyl separately or in combination induced *in vitro* micronucleus formation and sister-chromatid exchange induction in human lymphocytes and *in vivo* micronucleus induction in polychromatic erythrocytes of the rat bone-marrow. Sakr and Abdel-Samie (2008) reported that metalaxyl induced apoptosis and bax expression in hepatocytes of mice. Dasgupta et al. (2011) reported that residues of

buprofezin, chlorpyrifos, metalaxyl, and myclobutanil were detected in incurred grape and wine samples.

The potential role of dietary antioxidants to reduce the activity of free radical-induced reactions has drawn increasing attention. Ginger (*Zingiber officinale* Roscoe) is an example of botanicals which is gaining popularity amongst modern physicians and its underground rhizomes are the medicinally useful part (Mascolo et al. 1989). Ginger was found to relieve the symptoms of nausea and vomiting associated with motion sickness, surgery and pregnancy (Gilani and Rahman, 2005). The pharmacological effects of ginger and its pungent constituents, fresh and dried rhizome were investigated. Among the effects demonstrated are anti-platelet, antioxidant, anti-tumour, anti-rhinoviral, anti-hepatotoxicity, anti-arthritis and anti-diabetic effect (Fisher-Rasmussen et al. 1991, Sharma et al. 1994, Kamtchoving et al. 2002, Islam and Choi, 2008). Ginger was found to have hypocholesterolaemic effects and cause decrease in body weight, glucose in blood, serum total cholesterol and serum alkaline phosphatase in adult male rats (Bhandari et al., 2005). Ginger extract-pretreated rats attenuated in a dose-dependent manner, CCl₄ and acetaminophen-induced increases in the activities of ALT, AST, ALP, LDH and SDH in the blood serum (Yemitan and Izegebu, 2006). The present work was conducted to study the effect of ginger extract on the hepatotoxicity of the metalaxyl in albino mice.

2. Materials and Methods

Animals

Sexually mature male albino mice (*Mus musculus*) weighing 20 ± 5 g was used. The animals were housed in plastic cages (40×30×16 cm) and kept in the laboratory under constant temperature ($22 \pm 1^\circ\text{C}$) for at least one week before and along the period of the experimental work. They were maintained on a standard rodent diet composed of 20% casein, 15% corn oil, 55% corn starch, 5% salt mixture and 5% vitaminized starch. Water was available *ad libitum*.

Preparation of ginger aqueous extract

Ginger (*Z. officinale* Roscoe) rhizome was purchased from the local market at Shebin El-kom, Egypt. One kilogram fresh ginger rhizome was cleaned, washed under running tap water, cut into small pieces, air dried and powdered. 125 g of this powder were macerated in 1000 ml of distilled water for 12 h at room temperature and were then filtered. The concentration of the extract is 24 mg/ml. Each animal in the present study was orally given 1 ml of the final aqueous extract (Kamtchouing et al., 2002).

Experimental design

All the experiments were done in compliance with the guide for the care and use of laboratory animals (National Research Council, 1985). Animals were divided into 4 groups.

Group 1: Animals of this group (20 mice) were orally given metalaxyl by gastric intubation at a dose level of 1/10 LD₅₀ (130mg/kg body weight) three times per week for continuous 4 week (Sakr and Lamfon, 2005).

Group 2: Animals in this group (20 mice) were given the same dose of metalaxyl given to animals of group 1 followed by 1 ml of final aqueous extract of ginger (24 mg/ml) three times weekly for 4weeks. This dose of ginger was selected according to Sakr et al., (2011).

Group 3: Animals of this group (20 mice) were orally given ginger at the same dose level of group 2.

Group 4: This group is a control, in which animals (20 mice) were orally given water. 10 animals were selected randomly after 2 and 4 weeks of treatment and were sacrificed.

Histopathological examination

The treated animals and their controls were killed by cervical dislocation, quickly dissected and liver was removed, fixed in Bouin's fluid. After 24 h, tissues were rinsed three times in 70% ethanol, dehydrated using a graded ethanol series and then embedded in paraffin wax. Paraffin sections were cut into 5 micrometers thick slices and stained with

haematoxylin and eosin and examined under light microscope.

Biochemical assays

For enzymes determination, blood samples were collected from animals after 4 weeks of treatment. Sera were obtained by centrifugation of the blood sample and stored at -20°C until assayed for the biochemical parameters. Aspartate aminotransferase (AST) and alanine aminotransferase (ALT) were measured using a fully automated Hitachi 911 analyzer (Tokyo, Japan). A commercial randox kits (Randox Laboratories, LTD, Ardomre, Crumlin, United Kingdom) were used in these analysis. In hepatic tissue samples, the extent of lipid peroxidation was estimated as the concentration of thiobarbituric acid reactive product (malondialdehyde) according to (Ohkawa et al., 1979). Superoxide dismutase activity was measured using the methods of Rest and Spitznagel (1977). The principal of this method depends on the ability of SOD to inhibit the power of phenazine methosulphate mediated to reduce the nitroblue tetrazolium. Catalase activity was determined from the rate of decomposition of H₂O₂ (Aebi et al., 1974).

Statistical analysis

The results were expressed as mean \pm SD of different groups. The differences between the mean values were evaluated by ANOVA followed by Student's "t" test using Minitab 12 computer program (Minitab Inc., State Collage, P.A).

3. Results

i. Histological results

Liver of control animals or animals given ginger extract showed normal structure (Fig.1). Examination of liver of mice treated with metalaxyl displayed many histopathological alterations. After two weeks from the beginning of the administration of the fungicide, the liver tissue revealed disruption of normal cords arrangements of the hepatocytes and the intrahepatic blood vessels were congested (Fig.2). Infiltrations by large mass of leucocytic inflammatory cells were observed (Fig.3) and the hepatocytes displayed cytoplasmic vacuolization (Fig.4). The histopathological changes of the liver were more pronounced after four weeks where the hepatic cells appeared with giant nuclei and their cytoplasm contained fatty droplets (Fig.5). Animals treated with metalaxyl and ginger for two weeks revealed that some hepatocytes showed fat droplets (fig.6). Examination of liver sections after four weeks revealed that liver tissue restored its normal structure and most cells displayed a certain degree of recovery besides the appearance of some binucleated ones.

ii. Biochemical results

Change in ALT and AST:

Figure (7) showed the effect of different treatments on serum ALT activity. Non-significant difference in serum ALT activity was recorded in mice treated with ginger extract in comparison with control group. Animals treated with metalaxyl showed a significant increase in serum ALT activity after 2 and 4 weeks of treatment. On the other hand, animals treated with metalaxyl and ginger revealed a significant decrease in ALT activity when compared with metalaxyl group. Figure (8) showed non-significant difference in serum AST activity in animals treated with ginger when compared with control group. Animals treated with metalaxyl showed significant increase in serum AST activity while animals treated with metalaxyl and ginger showed a significant decrease in AST activity when compared with metalaxyl treated group.

Change in MDA, SOD and CAT:

Table (1) showed the effect of different treatments on malondialdehyde (MDA) (index of tissue lipid peroxidation), superoxide dismutase (SOD) and catalase (CAT) in liver of animals examined after 4 weeks. MDA level was increased significantly, whereas the activity of SOD and CAT was found to be decreased in metalaxyl-treated animals when compared to the control group. Treating rats with ginger and metalaxyl increased MDA level and returned SOD and CAT activity to nearly that of the control.

4. Discussion

Results obtained in the present study indicated that metalaxyl induced many histopathological alterations in the liver tissue of mice such as tissue impairment, congestion of intrahepatic blood vessels, cytoplasmic vacuolization of the hepatocytes and fatty degeneration. Similar results were reported by Sakr and Lamfon (2005) and they added that metalaxyl affected liver enzymes (transaminases) in mice. The alterations induced by metalaxyl were also observed in liver of some mammalian animals exposed to various fungicides. When male and female rats were exposed to mancozeb, the liver showed centrilobular necrosis with extramedullary haemopoiesis and the kidney showed tubular dilation, necrosis and congestion of blood vessels (Szepvolgyi *et al.*, 1989). Selmanoglu *et al.* (2001) revealed congestion of blood vessels, increase in number of Kupffer cells, cellular infiltration and hydropic degeneration in liver of male rats treated with carbendazim.

Treating animals with metalaxyl induced a significant increase in the oxidative stress, malondialdehyde which is lipid peroxidation marker and a significant decrease in the level of serum antioxidant enzymes, superoxide dismutase and catalase. Hanukoglu *et al.* (1993) reported that lipid peroxidation and reactive oxygen species are produced by electron leakage outside the electron transfer chains and these oxygen radicals can initiate lipid peroxidation, to inactivate P₄₅₀ enzymes. Mathews *et al.* (2000) mentioned that the damage occurred in the cell membrane by hydroxyl radicals induced oxidation of polyunsaturated fatty acids in membrane lipid in a process called lipid peroxidation. Moreover, Banks and Soliman (1997) recorded increase in serum hydroperoxides and decrease in reduced glutathione after benomyl toxicity in rats. The authors added that the *in vivo* toxicity of benomyl may be associated with oxidative stress. According to Calviello, *et al.* (2006) fungicides-induced damage is closely associated with increase in lipid peroxidation and the decrease in the antioxidant enzymes. Sakr *et al.* (2007) found that mancozeb fungicide induced a significant decrease in the serum antioxidant superoxide dismutase and an increase in malondialdehyde which is lipid peroxidation marker in albino rats. The Liver toxicity recorded in the present study may be due to the oxidative stress resulted from metalaxyl or its metabolite.

1. The obtained results showed that treating rats with metalaxyl and ginger improved the histopathological and biochemical changes induced in the liver by metalaxyl. This indicated the effectiveness of ginger in prevention of metalaxyl hepatotoxicity. The effect of ginger on hepatic damage was studied by some investigators. The effect of the ethanol extract of the rhizome of *Zingiber officinale* was tested against carbon tetrachloride and acetaminophen-induced liver toxicities in rats. CCl₄ and acetaminophen induced many histopathological changes and increased the activities of ALT, AST, ALP, LDH and SDH in the blood serum. Ginger extract was found to have a protective effect on CCl₄ and acetaminophen-induced damage as confirmed by histopathological examination of the liver (Yemitan and Izegbu, 2006). Bhandari *et al.* (2003) studied the effect of an ethanol extract of ginger on country-made liquor (CML)-induced liver injury in rats.

Fig.8. Effect of different treatments on serum ALT.

Table (1). Effect of Metalaxyl and/or ginger extracts on level of MDA, CAT and SOD activities in liver of mice.

Group	MAD (n mol/ml)	CAT (μ mol/ml)	SOD (μ mol/ml)
Control	15.5 \pm 1.5	6.5 \pm 1.2	140.5 \pm 5.5
Ginger	16.2 \pm 1.4	6.1 \pm 0.9	141.3 \pm 4.3
Metalaxyl	30.5 \pm 2.8*	2.5 \pm 0.6*	106.2 \pm 3.5*
Metalaxyl+Ginger	20.5 \pm 1.6	4.8 \pm 0.2	132.2 \pm 2.6

(*)Statistically significant ($P < 0.05$)

Their results showed that administration of ginger ethanolic extract (200 mg/kg) orally from day 15 to day 21 along with CML produced significant ($P < 0.01$) lowering of serum AST, ALT, ALP and tissue lipid peroxide levels. Moreover, ginger reduced the level of serum malondialdehyde acting as lipid peroxidation marker and increased the serum level of antioxidant enzyme, superoxide dismutase. Similarly, Siddaraju and Dharmesh (2007) reported that ginger-free phenolic and ginger hydrolysed phenolic fractions exhibited free radical scavenging, inhibition of lipid peroxidation, DNA protection and reducing power abilities indicating strong antioxidant properties. Ansari et al. (2006) showed that the ethanolic *Z. officinale* extract pretreatment for 20 days in

isoproterenol treated rats induced oxidative myocardial necrosis in rats, enhances the antioxidant defense (catalase, superoxide dismutase and tissue glutathione) and exhibits cardioprotection property. Ajith et al. (2007) reported that ginger ameliorated cisplatin-induced nephrotoxicity and this protection is mediated either by preventing the cisplatin-induced decline of renal antioxidant defense system or by their direct free radical scavenging activity. Amin and Hamza (2006) demonstrated that *Z. officinale* increased the activities of testicular antioxidant enzymes, superoxide dismutase, glutathione and catalase and reduced level of malondialdehyde. Ghasemzadeh et al. (2010) reported that young rhizome of *Z. officinale* had higher content of flavonoids with high antioxidant activity. Sakr et

al.(2011) reported that that ginger has ameliorative effect against kidney damage induced by metalaxyl and reduced lipid peroxidation and increased the serum level of antioxidant enzymes, SOD and CAT.

It is concluded from the present study that, ginger extract have protective effect against metalaxyl-induced hepatotoxicity. This effect may be mediated by free radicals scavenging activity of ginger.

Low Intensity Laser Versus Synthetic Bone Graft To Increase Bone Density After Enucleation Of Large Cystic Lesions Of Jaws

Khaled A. Elhayes

Corresponding author: pdkae@yahoo.com

Ass. Professor Oral& Maxillofacial Surgery, OMFS Department, Faculty of Oral& Dental Medicine, Cairo University.

Abstract: *Materials and Methods:* This study included 27 patients of both sex (17 males & 10 females) aged 20 - 48 years. They were divided into 3 groups, each group contained 9 Patients. All patients in all groups were selected to have large cystic cavities in their dental arches of different etiological factors, ranged in diameter 1.5 – 3.5 cm, and not approaching any vital structures. They underwent surgical enucleation of these cystic lesions. Patients of group (I) have received bone substitute in form of Algipore granules that were packed inside the bony cavities of enucleated cysts till complete filling. While Patients in group (II) have not received any grafting materials after cysts enucleation, but low intensity diode laser was applied to all of them in six sessions for each patient . Patients in group (III) ,control group, have not received any grafting materials after cysts enucleation. Radiographic evaluation of all patients was performed using digital radiography system (Digora). Radiographs were taken preoperatively and at intervals of 1 day, 6 weeks, 3 months and 6 months post surgically. The mean bone density at the same region of opposite side was also measured for comparison. *Results:* It was found that there was a significant higher bone density in Algipore group than other two groups at 1 day and 6 weeks time intervals, while there was no significant difference between Algipore and Laser groups at 3 months and 6 months post surgically. But both groups showed significantly higher bone density than control group at these 3 & 6 months time intervals. Furthermore, the bone density was significantly higher in Laser group than control group at 6 weeks time interval. In control group, there was no significant difference in bone density between all time intervals. In group I & II, there were significant increase in bone density in all time intervals compared with preoperative density, but, there were no significant difference in bone density between different time intervals in control group. *Conclusion:* Algipore (CORALS) can be a dependable bone substitute material for grafting bony defects in both jaws, Low intensity laser has also the ability to significantly increase bone density of empty cavities of jaws after enucleation of large cysts, so, it is preferred than Algipore specially with cases having infected lesions .

[Khaled A. Elhayes. **Low Intensity Laser Versus Synthetic Bone Graft To Increase Bone Density After Enucleation Of Large Cystic Lesions Of Jaws.** Journal of American Science 2011; 7(6):1101-1108]. (ISSN: 1545-1003). <http://www.americanscience.org>.

Key words: Bone substitute material, Diode laser

1.Introduction

Large bony spaces left after enucleation of large cystic cavities of the Jaws represent a questionable issue for bone grafting procedures. To increase the bone density, low intensity laser was found to have a significant rule for this purpose too, Khadra et al.,(2004).

Algipore was studied against Low Intensity Diode Laser to fulfill the aim of increasing bone density for these bony spaces.

Roux et al (1988) reported that Corals have the advantage of being cheap , easily sterilized, inert (99% of calcium carbonate), biodegradable and well

reossified. They shorten surgical procedures by avoiding the use of iliac and/or costal grafts. No infectious complications have been noted, Roux et al (1988). Patat and Guillemin (1989) mentioned that “Experimental studies commenced in 1977 and

human clinical applications commenced in 1979, have largely demonstrated the biocompatibility of the coral material and its entirely original nature. This biomaterial is progressively and totally replaced by newly formed bone with the characteristics of the recipient bone (after completion of the restoration process), Patat and Guillemin (1989). Begley et al

(1995) in a comparison between Corals and others, said that “a layer of what appeared as dense calcification was seen around the coral implant. Coral elicited no marked inflammatory response, and this was attributed to the negligible amounts of protein present in these materials . Roux et al (1995) mentioned that “Madreporic Coral graft implants can be recommended as bone substitute in cranial base surgery: 1) The material simplifies the surgical procedure; 2) Harvesting of autologous bone is no longer necessary; 3) Transmission of infections like AIDS, Hepatitis C or Creutzfeld-Jacob-disease can be avoided with certainty”. Demers et al (2002) in their review for Corals as a bone substitute revealed that the structure of the commonly used coral, is similar to that of cancellous bone and its initial mechanical properties resemble those of bone, they are biocompatible, osteoconductive, and biodegradable at variable rates, and they added “When applied appropriately, natural coral exoskeletons have been found to be impressive bone graft substitutes. Turhani et al (2005) concluded that the results of their study showed that Algipore obtained from calcified red algae support the proliferation and differentiation of human osteoblast-like cells on its surface.

Rochkind et al (2004) ; Fukuhara et al (2006) ; Pretel et al (2007) and De Oliveira et al (2008) all revealed that the use of infrared LLLT directly to the injured tissue showed a biostimulating effect on bone remodeling and tissue repair by stimulating the modulation of the initial inflammatory response and anticipating the resolution to normal conditions at the earlier periods of time.

Saito et al (1997) ; Khadra et al (2004) ; Nissan et al (2006) ; Lirani-Galvão et al (2006) and Miloro et al (2007) all suggested that laser therapy of low power density is effective on bone formation and the bone healing process by affecting calcium transport during new bone formation .

Kusakari et al (1992) and Stein et al (2008) revealed that, the LLLT appeared to increase bone-forming activity of osteoblasts or may directly act on osteoblast-precursors and biostimulate osteoblast-like cells for enhancement of bone regeneration. Vladimirov et al (2004) said that “Laser therapy based on the stimulating and healing action of light of low-intensity lasers (LLLT), along with laser surgery and photodynamic therapy, has been lately widely applied in the irradiation of human tissues in the

absence of exogenous photo-sensitizers. Besides LLLT, light-emitting diodes are used in phototherapy (photobiostimulation) whose action, like that of LLLT , depends on the radiation wavelength, dose, and distribution of light intensity in time. Dörtbudak et al (2000) concluded that, irradiation with a pulsed diode soft laser has a bio stimulating effect on osteoblasts, which might be used in osseointegration of dental implants, Dörtbudak et al.,(2000).In bone grafting procedures, Many methods were used for measurement of bone density as dual X-ray absorptiometry, Bettin et al.,(2003); Johansson et al.,(2004); Kastl et al.,(2005); Marcen et al.,(2005).Peripheral quantitative computed tomography (pQ-CT) ,Butterfield et al.,(2005)· Micro-computed tomography (micro CT), Lu and Rabie (2004); Mankani et al.,(2004), Cutting torque measurements, Kastl et al.,(2005) and many other techniques. Sivarajasingam et al (2001) have measured Optical density of iliac and tibial grafts using a computerized densitometer, and compared them at 6 days, 6 weeks, and 3 months. Mankani MH. et al (2004) Concluded that the use of quantitative CT offers a practical approach for the non-invasive determination of new bone formation in mineralizing bone marrow stromal cells and hydroxyapatite-tricalcium phosphate(HA-TCP) transplants, Mankani et al.,(2004). Beltrame et al (2005) have presented an innovative calibration algorithm for a semi-quantitative analysis of non-standardized digitized X-ray images to investigate the progression of the new bone deposition and the osteo-integration at the bone-implant interface. Sanchez et al (2005) have measured the bone mineral density (BMD) and bone mineral content (BMC) by peripheral dual X-ray absorptiometry densitometer. Thorwarth et al (2005) used micro-radiography analysis for mineralization of autogenous bone grafts harvested from different sites concluded that the differences in mineralization depending on the origin of autogenous bone. Even after 6 months, these values could still be correlated to the transplants origin. Vossen et al (2005) have studied Bone quality pre- and post-transplant using other modalities by measuring acoustic velocity and density and by calculating elastic coefficients.

Aim of this study was to evaluate low intensity laser for increasing bone density in large bony cavities created by enucleation of large cysts of the jaws and also to compare between Low Intensity Diode Laser

and Corals as a bone substitute grafting material for filling these large bony cavities. In addition we aimed to Compare between the effect of grafting, non-grafting and Laser application procedures on bone densities of these cavities.

2. Material & Methods

2.1. Materials:

2.1.1. The Studied sample:

This study included 27 patients of both sex (17 males & 10 females) aged 20 - 48 years, they were divided into 3 groups:

Group I (Algipore Group): Contained 9 patients (4 males & 5 females) of average age 29.8 years.

Group II (Laser Group): Contained 9 patients (3 males & 6 females) of average age 31.85 years.

Group III (Control Group): Contained 9 patients (5 males & 4 females) of average age 30.95 years. All patients in all groups were selected to have large cystic cavities in their dental arches of different etiological factors, ranged in diameter 1.5 – 3.5 cm. and not encroaching any vital structures. (*Figure 1*)

Figure 1: Large cystic lesion of left Maxilla

All patients underwent surgical enucleations of these cystic cavities using either pyramidal flaps or semi-lunar flaps according to the location of the cyst in

relation to the crest of the ridge. (*Figure 2*)

Figure 2: Surgical enucleation of lesions in 3 cases representing the 3 groups
(Above; are lesions in place & Below; are Cavities after lesions enucleation)

2.2. Methods:

2.2.1. Root canal treatments:

Root canal treatments were performed to the related affected teeth before or during the surgical procedures.

Patients in group (I) have received bone substitute graft in form of Algipore granules that were mixed with a blood sample from the patient, then, packed inside the bony cavities of enucleated cysts till complete filling of these cavities. (*Figure 3*)

Figure 3: Algipore granules are packed inside the cavity of enucleated cyst

Patients in group (II) have not received any grafting materials after cysts enucleation, but Low Intensity Diode Laser was applied to bony cavities of all of them in six sessions for each patient, day after day starting from 1 day post surgical.

2.2.2. Laser Procedure:

Quanta system apparatus was used, the wave length used was 980 nanometres (nm), the power was 0.1 watt (W), and the laser beam emission was in continuous mode. (Figure 4)

The fibre used with this device was 320 micron (μm).

Figure 4: Diode Laser Device

Diode laser application was done with the fibre placed in direct contact with the tissues. Laser beam has been applied to the bony cavity labially and palatally, the time of each application was 60 seconds for each 1cm width of the cavity (Figure 5)

Figure 5: Application of Diode laser intraorally (labially & palatally)
The total energy for each 1cm. width of the cavity was 12 Joule (J), (6 Joule labially and 6 Joule palatally) as: $\text{Joule (J)} = \text{Watt (W)} \times \text{seconds (S)}$

Green eye glasses were worn by doctor and patient during laser application for eye protection.

Patients in group (III) have not received neither grafting materials nor Laser application after cysts enucleation, they represented the Control group. Suturing of the flaps for all patients was performed using 000 black silk suture without placement of any

guided bone regeneration membranes, then, postoperative regimen of medications was prescribed for the patients. (Figure 6)

Figure 6: Suturing of the flap (Up) & 6 months postsurgical (Down)

2.2.3. Radiographic evaluation:

Radiographic evaluation of all patients was performed using digital radiography system (Digora) by Soredex Orion Corporation version 1.51. Radiographs were taken preoperatively and at time intervals of 1 day, 6 week, 3 month and 6 months post-surgically. All radiographs were taken using long cone parallel technique with the help of bite blocks to provide standardization of images or digital panoramic radiographs were obtained. The mean bone density at the same region of opposite side was also measured for comparison.

The density measurement window displayed the radiographs, and a rectangular area is marked on the image in the area of the bony defects and area measuring was performed. The mean density of pixels within the area of cavity was recorded and the other normal side too. Results were displayed as numeric statistical information, as a histogram showing density distribution, and a density profile. (Figure 7)

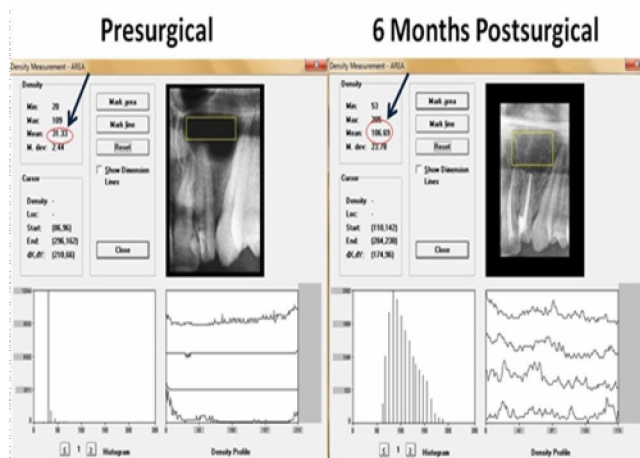

Figure 7: Measurement of bone density by DIGORA

2.2.4. Statistical analysis:

The data were tabulated and statistically analyzed using 2 ways ANOVA.

3. Results

At one day postoperatively: bone density in the Aligpore group showed significantly higher levels than both laser and control groups whose values were insignificantly different.

At six weeks postoperatively: Aligpore group still showed significantly higher bone density than both laser and control group, with another statistically significant higher bone density in laser group than control group.

At three months postoperatively: there was no statistically significant difference between bone density values of Aligpore and Laser groups, while both showed statistically significant higher levels than control group.

At six months postoperatively: there was no statistically significant difference between bone density values of Aligpore and Laser groups, while both showed statistically significant higher bone density than control group. (Figure 8)

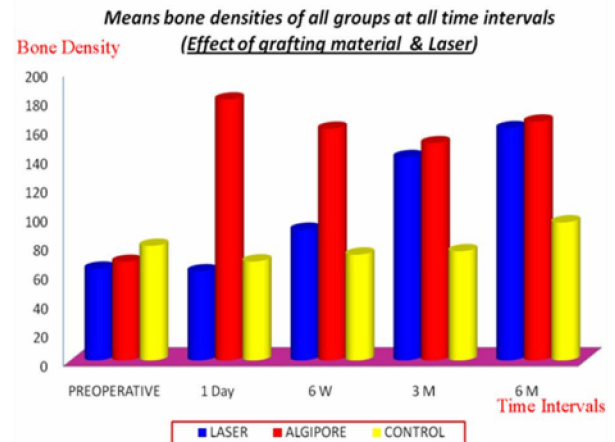

Figure 8: Mean values of Bone densities in all groups at different time intervals

In the laser group: there was no significant change in the bone density between preoperative and one day values, while there was statistically significant increase from 1 day to 6 weeks, from 6 weeks to 3 months and from 3 months to 6 months intervals.

In the Aligpore group: there was statistically significant increase from preoperative to 1 day intervals, there was statistically significant decrease from 1 day to 6 weeks postoperative intervals, followed by insignificant decrease from 6 weeks to 3 months, then there was statistically significant increase from 3 months to 6 months postoperatively.

In Control group: there was statistically insignificant decrease from preoperative to 1 day postoperative bone density values, followed by statistically insignificant increase from 1 day to 6 weeks, and another insignificant increase from 6 weeks to 3 month interval, then there was statistically significant increase from 3 months to 6 months. (Figure 9)

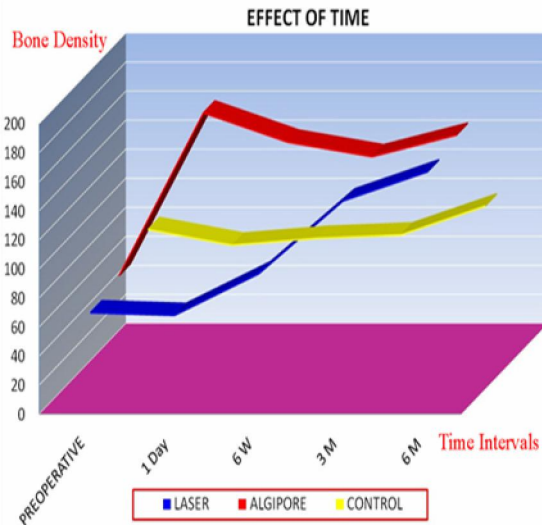

Figure 9: Effect of time on bone density in all groups throughout follow up periods

Difference was considered statistically significant at $p < 0.1$

Vertically : Evaluating effect of time on bone density in each group separately

4. Discussion

The corals were selected for this research as they are more available and cheaper than many other grafting materials, at the same time, the differences between corals and these various grafting materials were not significant, Velich et al., (2004). Corals also have no significant difference in bone density from autogenous bone grafts throughout time interval periods, Block et al.,(1998).

Algipore group had demonstrated better bone density than control group during all follow up periods that was in agreement with Sanchez et al, (2005) who have found that the bony defects where demineralized freeze-dried bone graft (DFDBG) was used, either with or without platelet-rich plasma (PRP), did demonstrate slightly greater Bone Mineral Density (BMD) and Bone Mineral Content (BMC) than those left untreated. Digital radiography was used to measure bone density as it could detect minute changes in density Jeffcoat(1993). Density measurement is used for providing an accurate measuring of gray scale values than the human eye can. The density of an image refers to its brightness. The maximum density value is 255, which corresponds to white. The minimum density value is zero, which corresponds to black. The different shades of gray have density values from 1 to 254 , Wenzel(1993). The bone density was significantly higher in laser group compared with control group at 6 weeks, 3 months and 6 months time intervals due to the ability of low intensity laser to increase bone density at the area of application. This was in agreement with (Khadra et al, 2004 ; Lirani-Galvão et al, 2006; Miloro et al, 2007; Nissan et al, 2006 ; and Saito et al,1997) who suggested that laser therapy of low power density is effective on bone formation and the bone healing process by affecting calcium transport during new bone formation.

In Conclusion : Algipore (CORALS) can be a dependable bone substitute material for grafting bony defects in both jaws, Low Intensity Laser has also the ability to significantly increase bone density of empty cavities of jaws after enucleation of large cysts, so, it is preferred than Algipore specially with cases having infected lesions .

Abstract: Taking a look at the asymmetry of the current data at the market, the present research tries to attain some conclusions regarding the stock share holders and investors' responses towards the financial leverage and issuing of audited financial reports within seven transactional days before event (issuing financial reports) Compared to seven transactional days after event. With the application of the nonparametric tests in two cross sectional and pooled method amongst the companies which are member of Tehran Stock Exchange organization from 13 industries, the reactions toward the prices was measured by making use of four liquidity Proxies within the period of 2002-2007. The results showed a weak relation between the leverage and the liquidity ranking, and other variables including the proportional spread of stock price, Stock Price Depth and number of stocks circulation times (Turnover Rate of Stock), did not demonstrate a significant relation. The results show that the capital structure is a related and dependent factor (even if the weak one) for decisions made by the investors and the shareholders. In fact, they consider the risk of cash flows resulted from debts in their decision-making process parameters. [Ali Ahmadzadeh and Ameneh Malekinejad. Survey of Relationship between the Capital Structure and Stocks Liquidity at the Accepted Companies in Tehran Stock Exchange Organization. Journal of American Science 2011;7(6):1109-1118]. (ISSN: 1545-1003). <http://www.americanscience.org>.

Keywords: Spread of stock price, Stock Price Depth, Turnover Rate of Stock, Liquidity ranking and Asymmetric information.

1. Introduction

The capital structure is the mixture of long-term fund resources being used by the companies by means of which the financial supply of assets can be paid. The mixture of debt and the capital affects the value of the companies through the expected incomes resulting from capitals and the rate of capital expense. Changing this mixture, results in the modification of capital cost of the company. The main goal of capital structure is providing an appropriate combination of the long-term fund resources in order to minimize the capital cost of the company, thereby, maximizing its marketing value. This mixture is called "the optimized structure". The most important concepts for investment decision makings involve management and shareholders attitude, risk and return. The term "return rate" is applied in order to explain increasing or decreasing rate of investment during period of maintaining assets. The expected "return rate" informs the investor of the average reward which he/she anticipates is achieved within a certain period. The difference between the anticipation and reality which is probably resulting from unanticipated changes and evolutions is called the uncertainty of the stock return. The investor is always in search of risk reduction and increasing certainty of investment

profitability. Several factors lead to the deviation of the return rate and as a result, change of the stock price at the market including commercial risk, interest rate risk, risk of inflation, financial risk, risk of liquidity and risk of exchange rate. Illiquidity as a risk causes the enhancement of the shareholders expected return and their response against its fluctuations. The liquidity points out the acceleration and expense of trading an asset or stock in an active market. The more precise the recognition of buyer and seller and their evaluation from an asset, the rate of exchange will be increased and its expense will be decreased, and as a result, the degree of liquidity is increased. In fact, the more the seller is able to sell the asset quicker and with lower cost, the more the liquidity will be (Gelosten, 1985). In investment market, risk and the return are positively correlated. The risk of liquidity resulting from asymmetry of the information has a highly important effect on the return rate demanded by the shareholder and is influenced by many factors including financial (validity) leverage. Lismer, Kouner and Sanbeth (2008) in a research done in the United States concluded that changes of leverage solely justify 20% of the liquidity periodical changes (E. Lismond, 2003). Barath, Paskarliu and woo (2008) proved that those companies who have replaced debt with the

capital, economically and statistically faced with considerable amount of liquidity cost changes which originates from increase of information asymmetry (Mac Groat, 2008). Amihud and Mendleson (1989) maintained that the increase in capital through debt can lead toward increasing asymmetry of information about the capital and by increasing the liquidity cost it will result in the enhancement of the capital.

2. Literature Review

The key parameter regarding efficiency of the financial markets structure is the expense of transactions. Most markets suggest different prices for the sellers and buyers, therefore the performance efficiency of the market can be measured by means of the price spread of the purchase request suggested by sellers. In case the suggested and requested prices are more close to the quoted price, this indicates the effectiveness of the market in appropriate pricing of that asset or stock (Sibilkov, 2007). The quality of disclosure is discussed as one of the most influential factors on the liquidity of an asset in the market which due to having some effects on the reduction of informational asymmetry and reduction of risk of variant selecting which can result in reducing capital expense of the companies. Amihud and Mendleson stated that since the liquidity increases the value of a company, the companies are more motivated to opt for the liquidity enhancement policies for securities (A. Lambert, 2006). In some cases, the problem is similar to the thing that Akarloff (1970) firstly introduced. He maintained that the informational asymmetry may result in pricing below or above the shares value of the companies. This issue effects the investment decisions made by investors and financial supply of the management. The management requires supply of funds in order to accept or reject the current positive net value projects, under such a circumstance, the decision to issuance stocks is dependent on the market status and asymmetry of the current information. In a manner that the shareholders are not able to have a prompt vision towards the company's situation, they may consider such issuance of stocks as a bad omen and a sign of financial weakness of the company and lower the price of their shares. The asymmetry issue is a problem which affects most often during the issuing of new shares which are used for financial supply of the company's new investments and lead to lowering the price of stocks. If the management goal is to maximize the return for all shareholders, the result will be the attainment of more cash amounts by the new investors in comparison with the previous ones. This may result in non acceptance of the project in the related field, even if it has a positive net value. This fact according which the liquidity via company

<http://www.americanscience.org>

decision makings can increase the value of companies indicated that the increase of liquidity can also decrease the cost of capital (Skinner, 1991). In order to have better understanding of the effect of liquidity on the capital structure of the company, one can look at the capital's cost of the company (taking the literature of the market internal structure into account which indicated the effect of illiquidity over the profit expected by the shareholder). The theoretical literature of the asset pricing states that the uninformed sellers who transact against those informed buyers demand more return rate for the relatively non-liquidated securities (Frider, 2006). Amihud and Mendleson (1986) stated that the higher cost related to transaction of stocks with low liquidity has led to higher claimed return rate and the mere liquidity demand generates higher capital cost. They claim that higher asset maintenance period allows the investors to gain higher expected return/gain by keeping a wide range of assets and as a result of effect of net cost of transaction. The studies all express that investors having assets with more liquidity should pay more amount and they request to be compensated for bearing amounts related to illiquidity. The validity of company can also be increased by reduction of the costs of inflation. Gloston and Milgram (1985), who dealt with the study of relationship between the risk and the price difference for the suggested trade by both seller and purchaser demonstrated that the accounting-specific ratios (including percent of paid profit, size of asset and growth of asset) as the risk parameters have a negative relation with price difference suggested for sale transaction of shares. They proved that the expenses of variant selection results from uncertainty about the future liquidity value of that asset. Their research was based on this concept that the difference of price recommended for sale is merely an informational phenomenon. The quality of information exposure and publicity at the market and the manner of data analysis by the users are to different and important aspects in the market that highly influences the liquidity of shares. Kupland and Galie (1983) decided to define a model for the informational asymmetry. In line with this, they demonstrated that the asymmetry of information in the market leads to increase of the price spread. W. Butler, Groleun and Weston (2002) proved that the liquidity of the capital market is an important determining factor of enlargement cost of capital. Those researchers found in their study that after monitoring the other factors, the investment banks bear lower costs for companies having higher liquidity rates. In fact, the companies with more cashable shares have lower capital cost. W. Anderson (2002) while mentioning the relationship between

total leverage and the company's liquidity rendered a model which anticipated that long-term usage of high debt amount will result in high level maintenance of assets having high liquidities. They found some evidence regarding the existence of a positive relation between leverage and maintenance of liquidity assets, and based upon such findings, they introduced a correlated loop for high leverage, high liquidity and slower growth. Mortal and L. Lipson concluded that companies having stocks with higher liquidity rates are more inclined to apply lower financial leverage and act for their financial provisions through the stocks. Frieder and Martel (2006) Assuming that the debt obliges managers to make better investment decisions found that, while the leverage increases, the scope of suggested price of the sale of stocks decreases. Besides, when the liquidity decreases, the leverage increases. In fact, while the expense for financial supply increases through shares the managers usually seek for using debts. Their results showed that one percent of increase in the spread will lead toward 3% of leverage enhancement. Buhler and Tib (2006) concluded that liquidity risk has a determining impact on the value of the market of company and an optimized leverage. The debt validity scope at the basic market also depends on the degree of liquidity risk. Ratio of debt against high capital in their model will result in lower validity scope. Adrian and Song shine (2008) found a strong positive relation between changing leverage and changing the size of balance sheet (change of asset). They also found that the financial intermediaries are able to moderate their balance sheets in such a way that they will have high financial leverage during high liquidity period and will have low financial leverage during the recession period.

3. Questions and Research Hypotheses

This research evaluates the proportional spread of stock price, Stock Price Depth and number of times of stock circulation (Turnover Rate of Stock) during the issuing of audited financial reports (the balance sheet) by the application of the suggested prices for sale of stocks in order to assess the followings:

Is there any relationship between the capital structure and liquidity of stocks of companies being accepted at the exchange market?

In order to answer the above question and taking the existing theoretical basics of it into account, one group of main hypotheses and one group of sub-hypotheses have been formulated as the following:

3.1. Main Hypotheses

1. There is a relation between ratio of the long-term debt toward long term assets and average of spread of stock price.

2. There is a relation between the ratio of the long-term debt toward long term assets and average of Stock Price Depth.
3. There is a relation between the ratio of long-term debt to long term assets and the average of Turnover Rate of Stock.
4. There is a relation between the ratio of long-term debt to long term assets and the rank of the stock liquidity.

3.2. Sub-Hypotheses

1. There is a difference between the average of difference spread of stock price(C Spread) of the leveraged companies and the non-leveraged ones.
2. There is a difference between the average of difference of stock price depths(C Depth) in leverage companies and the one in the non-leveraged ones.
3. There is a difference between the average of difference of Turnover Rate of Stock (C Turnover Rate) of leveraged companies and the non-leveraged ones.
4. There is difference between the average of stock liquidity rank of leveraged companies and the non-leveraged companies.

4. The Methodology of Research

The current research is of applied type and since it is based on the generalization of information coming from a small portion of society named as sample and also because the variables are studied without any alterations, it is also analytical. The duration of the current research was selected by taking the approximate duration of more activities of Tehran Stock Exchange market and ease of access of exchange data into consideration, and a period of 6 years from the year 2002 till 2007 was selected for the financial reports of the companies.

5. Statistical Sample Selection Terms and Conditions

By considering the independent and dependent research variables which includes capital structure and stocks liquidity (which requires the application of exchange of companies' information) the following limitations were defined for selecting sample containing most active companies during the states period:

1. The companies which have been a member of Tehran Stock Exchange during 2002 and their membership have been continued till the year 2007.
2. All companies that their financial year ends in 12.29.
3. All financial moderating and investing companies were omitted from the sample list.

4. All companies who have the data required by research (enough financial Reports) during the above time duration.
5. Companies that during the above 6 years period have less than 6 months of Inactivity (non conduct of stock trades registered at the Trade Panel).
6. The companies which have at least 5 registered trades within each of one month periods before and after the date of publicizing audited financial reports.

In general and after imposing the above restrictions and conditions, there remained 57 companies out of 13 industries all of which were evaluated and tested as the statistical sample. The theoretical basics of the research has been collected from various Persian and Foreign articles and translated books and the data related to the research variables includes data gained by the financial reports and dates of issuance via Tadbir Pardaz and Pars Portfolio software, and also the data regarding price and volume of transactions has been gathered from the Exchange Information Software by paying attention to bulk transactions omission requirement and also ease of having access to that information. After the collecting procedure was finished, the data has been examined with two cross sectional and whole annual methods and after assessing variables, the SPSS software was applied in order to make some statistical evaluations. After the test for determining normality of data, the type of the required test for assessing each hypothesis was determined. In such a manner that Pearson correlation test has been applied for main hypothetic test and also for testing secondary theories (difference of mean between two independent groups of the leveraged and non-leveraged companies) the Kroschall-valis test was used. In case of existence of relation between variables, the Regression Equation has been applied. In order to perform tests, firstly the leverage of companies has been calculated and the mean of leverages of each year has been considered separately. In the next phase, companies having leverages more than or equal to the mean were considered as the leveraged companies and the companies with leverage lower than the mean were considered as non leveraged companies.

6. Measuring Research Variables

6.1. Independent Variable

6.1.1. Capital Structure

It points to the left side of the balance sheet and by means of mixture of the long-term funds resources the payments for the financial supply of the assets are arranged.

a) Ratio of the long-term debts to long term assets:

$$L_{it} = (LD/LA) \times 100 \quad (1)$$

In which:

L = Leverage
 LD = Long-term debts
 LA = Long term assets
 i= i company
 t= year of t

6.2. Dependent Variable

The liquidity points to traded asset with lower cost and higher speed. In this research, liquidity means liquidity of the “stocks” of a company and for measuring it, following four parameters have been defined:

a) Proportional spread of stock price

$$SPREAD_i = \frac{AP - BP}{(AP + BP)/2} \times 100 \quad (2)$$

b) Stock Price Depth

$$DEPTH = \frac{TAP}{TBP} \times 100 \quad (3)$$

c) Number of frequency of stocks circulation

$$TURN\ OVER = \frac{NST}{NSO} \times 100 \quad (4)$$

d) Liquidity ranks or score (through symmetrical mean of the six parameters):

$$M_j = N / \left(\frac{1}{I} \right) \quad i = 1.2, \dots, N = 1.2, \dots, 6 \quad (5)$$

In which:

SPREAD= Total ration of relative price gap for company i in the time period t

AP (ask Price) = Average of price requested by purchaser during t

BP (Bid Price) = Average of the seller' suggested price during t

TAP = Total value of stocks requested by the buyer

TBP= Total value of stocks suggested by the seller

NST = Number of Stocks Traded

NSO= Number of Stocks Outstanding

M_j= j M investment company

N= Number of sextet indicators

I = Indicator of I M from the series (Number of traded stocks, Value of traded stocks, Number of trade days, Number of times of accomplished trade, average of the number of distributed stock and average of the existing value of company stocks)

T= time duration under study

I = Sample under study

Since the goal of evaluation of stockholders and investors' reactions in the short run against the issuance of financial reports and companies' capital structure, therefore the average of 7 days before and 7 days after issuance of financial reports were calculated and similar to Kanagartenam, J.louboo and J.Valen method, the average data before the event (issuance of the audited financial reports) was

calculated as the proxy for each of the spread, depth and Turnover Rate of Stock variables.

The following indexes are defined during this phase:

$$C \text{ SPREAD} = \text{SPREAD}_{t+1} - \text{SPREAD}_{t-1}$$

$$C \text{ DEPTH} = \text{DEPTH}_{t+1} - \text{DEPTH}_{t-1}$$

$$C \text{ TURNOVER} = \text{TURNOVER}_{t+1} - \text{TURNOVER}_{t-1}$$

C SPREAD = the difference of proportional price spread

C Depth = the difference of stocks depth

C TURNOVER = the difference of number of times of stocks circulation

SPREAD_{t-1} and $t+1$ = the average percent of the proportional spread of stock price in period before and after the event (Issuance of audited financial reports)

DEPTH_{t-1} and $t+1$ = the average stocks depth in the period before and after the event (Issuance of audited financial reports)

TURNOVER_{t-1} and $t+1$ = the average index of stock circulation in the period before and after the event (Issuance of audited financial reports)

(The liquidity rank has been considered as total and as annual total average point and the test and its analyses are done annually and distinct from way of calculating other 2 parameters where the periods before and after the event have been considered).

6.3. Controller Variables

In this research, the following variables have been used as a controlling variable for removing their effects on the dependent variable:

1. Size of the company: Equal to the natural logarithm of the company's asset book value.

2. Stock return: Equal to annual average of the price difference at the beginning and end of trading period of the stocks plus Cash Dividends by price of the start of the period.
3. Cash Dividends: equal to the amount of distributed liquidated profit among the shareholders.
4. Return of the assets: The parameter is the profitability of the company which has been calculated as percentage of ratio of the net income to the total assets book value.

7. Test Hypotheses

7.1. Main Hypotheses

This group of hypothesis deals with the study of existence of relation between the capital structure and the liquidity of shares. In order to test the above theories and studying the existence of a significant relation and determining type and degree of the relation which exist between capital structure and liquidation, the Pearson's correlation test and correlation analysis has been used. Comparing significance level with the test level (0.05) in cross sectional method is a good indicator of non existence of significant relation between leverage and variables for liquidity per each year. In other words, the difference of spread, depth and rank of liquidity showed the correlation coefficients of respectively 0.369, 0.33 and 0.336 and significance level of 0.005, 0.012 and 0.011 in the year 2002 and in the year 2004, the sole rank of liquidity had 0.00 significance level of 0.449 correlation coefficient with having leverage.

Table1. Correlation test between liquidity variables and leverage in cross sectional method

Title	Description	1381	1382	1383	1384	1385	1386	Test Result
Spread and Leverage	Correlation Coefficient	0.369	0.096	-0.064	-0.156	0.023	0.09	Reject of hypothesis H1
	Significance level	0.005	0.259	0.635	0.247	0.866	0.251	
Depth and Leverage	Correlation Coefficient	-0.330	0.46	0.069	0.199	-0.024	0.075	Reject of hypothesis H1
	Significance level	0.012	0.168	0.612	0.139	0.86	0.428	
Turnover Rate and leverage	Correlation Coefficient	-0.158	0.086	-0.052	0.085	-0.220	0.421	Reject of hypothesis H1
	Significance level	0.241	0.437	0.703	0.531	0.1	0.006	
Liquidity rank and leverage	Correlation Coefficient	0.336	0.37	0.449	0.068	0.076	0.038	Reject of hypothesis H1
	Significance level	0.011	0.494	0.000	0.617	0.574	0.12	

Due to largeness of significance level out of test level (in general format), all of the above results ended in

<http://www.americanscience.org>

rejection of H1 hypothesis. However, based on the pooled method the rank of liquidity has correlation

editor@americanscience.org

coefficient of 0.22 with significance level of 0.003. As follows, the summary of the results of this test have been given by the method of total years.

Table 2. Result of correlation test between liquidity variables and leverage

Leverage	Pearson Correlation Coefficient	Significance Level	Test Level	Test Result
Difference of Spread and leverage	0.024	0.687	0.05	Reject of Hypothesis H1
Difference of Depth and leverage	0.007	0.906	0.05	Reject of Hypothesis H1
Difference of Turnover Rate and leverage	-0.080	0.176	0.05	Reject of Hypothesis H1
Difference of leverage rank and leverage	0.22	0.003	0.05	Reject of Hypothesis H0

Due to significance of the correlation test only in the method of the total years, the regression test was performed between dependent variables (liquidity) and independent variable (leverage) and all controlling variables (return, Cash Dividends, profitability, size). In this test, only the rank of liquidity also had a linear relation in the model. The determination coefficient of 0.151 and the moderated determination coefficient of 0.132 show that 0.132

percent of modifications of liquidity rank are anticipated by these variables. The significance of the total Regression Model is evaluated by ANOVA test and then the significance of individual coefficients is reviewed by the table of coefficients. The purpose of analysis of the regression variance is to evaluate the certainty about existence of a linear relation between the two variables.

Table 3. Analysis of ANOVA and Durbin Watson's Test

Description	Watson Durbin statistics	Determination Factor	Moderated determination factor	F statistics	Significance level	Result
Leverage and Spread	1.978	0.011	-0.011	0.612	0.802	There is no linear relation
Leverage and depth	1.914	0.014	-0.008	0.738	0.713	There is no linear relation
Turnover Rate and leverage	2.233	0.004	-0.018	0.148	0.981	There is no linear relation
Liquidly and leverage	1.723	0.151	0.132	0.619	0.000	There is no linear relation

Since Durbin Watson's statistics in the above table are placed at 1.5 till 2.5 time span which indicate the nonexistence of correlation among errors. In addition, because all achieved significance levels in the hatched boxes (liquidity rank and leverage) are less

than 0.05; they indicate the existence of a linear relation between mentioned variables and the model.

8. Leverage, Liquidity Rank and Controlling Variables

Table4. Liquidity variables significance coefficient & leverage at Regression Model based on pooled method

Variable	Non standardized coefficient		Standardized coefficients	t	Significance level
Fixed Coefficient	150.266	17.113		8.781	0
Leverage	0.671	0.218	0.178	3.083	0.002
Profit	-0.205	0.044	-0.268	-4.61	0
Cash Dividend	-0.004	0.003	-0.079	-1.297	0.196
Profitability	-0.252	0.335	-0.046	-0.753	0.452
Size	-4.061	1.215	-0.193	-3.343	0.001

• By Studying the coefficient table well indicates the significance of some of coefficients (the hatched boxes) in the equation related to the leverage and liquidity rank. During the total model fitting,

fixed coefficient, first type leverage, return and size showed a significance level lower than 0.05. The aforesaid variables were fitness retested in order to estimate the main model.

Table5. Durbin Watson's test and final model determination coefficient

Model	Correlation Coefficient	Determination Coefficient	Moderated determination coefficient	Estimate standard deviation	Durbin Watson Statistics
1	0.376	0.141	0.132	63.55	1.708

Table6. Coefficients and significance level at the final model

Variable	Non standardized Coefficients		Standardized coefficients	t	Significance level
Fix coefficient	137.496	15.91	_____	8.642	0
Leverage	0.795	0.207	0.214	3.845	0
Profit	-0.199	0.041	-0.275	-4.869	0
Size	-4.07	1.198	-0.193	-3.396	0.001

• In this manner, one estimates the following linear relation between the rank and leverage

• of liquidity and controlling variables by considering Durbin Watson and Linearity of the Tests of Model:

$$LD = 137.496 + 0.795L - 0.199 RE - 4.070 S \quad (6)$$

In which:

LD (Liquidity Degree) = Average of the company's liquidity annual rank

L = Average of annual leverage (ratio of long-term debt to long term Assets)

RE = Average of the annual stocks return of the company

S = the size of the company (Total of the assets)

= Measurement error

This groups of theories deals with the existence of a significance difference between each of liquidity parameters in two leveraged and non leveraged independent companies. Results achieved by testing this group of theories in two cross sectional and total year methods showed that there is no significance difference between each one of liquidity variables of these two groups of companies. These results gained by Kroschall-valis test, have resulted in acceptance of H_1 only during the year 2004. Similarly, these two groups of companies demonstrated a significant difference with each other by 0.043 of significant difference between difference of spread, 0.39 between difference of depth and 0.001 significant differences between liquidity ranks of two groups.

9. Secondary Theories

<http://www.americanscience.org>

Table7. Difference and significance level of liquidity and leverage variables in two leveraged and non leveraged groups

Title	Description	2002	2003	2004	2005	2006	2007	The Test result
Spread between the two groups	Average difference	-0.72	-0.05	0.89	0.64	-0.29	-0.35	Reject of Hypothesis H1
	Significance difference	0.762	0.873	0.043	0.702	0.649	0.541	
Depth between the two groups	Average difference	0.43	-0.02	-0.87	-0.74	0.86	-0.840	Reject of Hypothesis H1
	Significance difference	0.598	0.823	0.043	0.296	0.643	0.084	
Circulation between the two groups	Average difference	-0.61	1.19	-0.15	0.16	-0.42	-0.609	Reject of Hypothesis H1
	Significance difference	0.151	0.196	0.238	0.33	0.898	0.004	
Liquidity rank between two groups	Average difference	-27	12	-0.68	-12	-.11	-0.215	Reject of Hypothesis H1
	Significance difference	0.091	0.444	0.001	0.598	0.555	0.098	

The decision-making principle in this rest can also be the comparison of the significance level with the test level (0.05). Taking the achieved results in the above table into consideration, with 95% of certainty it can be stated that only the spread, depth and rank of liquidity of two leveraged and non leveraged groups of companies have had a significance difference with each other and in remaining years none of the liquidity variables did not demonstrate a significance difference in these two groups. However, on total years method, the rank of liquidity with significance

level of 0.002 rejected zero hypothesis and demonstrated a significant difference between these two groups of companies which in total one can mention that: The liquidity rank of non-leveraged companies is lesser(better) than the rank of the leveraged ones. In other words, one can express that the investors prefer the companies which have lower leverage than those having higher leverage. In the following part, the results of this test based on the pooled method:

Table8. Difference and significance level of liquidity and leverage in two leveraged and non-leveraged groups by pooled method

Year	Leveraged companies mean	Not leveraged companies mean	Significance level	Test Level	Test Result
Spread	0.373	0.502	0.367	0.05	Reject of Hypothesis H1
Depth	-0.431	-0.650	0.143	0.05	Reject of Hypothesis H1
Circulation	0.258	0.390	0.928	0.05	Reject of Hypothesis H1
Liquidity Rank	115	87	0.002	0.05	Reject of Hypothesis H1

Leverage is among those subjects the increase of which can influence the risk of the investor and his/her expected return. Since all shareholders have their own extra payments, it is not reasonable that we expect them to pay attention and react toward the increase of leverage and as a result toward increasing the possibility of bankruptcy. However, as it was mentioned in the result, while making decisions by the investors, the amount of debt used by the companies has had lower priority and the investors do not pay considerable reactions against increase of debt. Regarding the long-term debt, one can mention that due to the fact that the long-term debts allocate a small section from the left side of the balance sheet, perhaps one may anticipate the behavior of the investor and his/her lack of attention toward the long-term debts (which is necessary to mention that the major part of the long-term debts consists of retirement benefit provision). It is worth mentioning that the event and date of publication considered by this research may be the date of issuance of the audited financial reports being selected due to its more reliability. However, one should not ignore this reality that the disclosure of information in Iranian market results in considerable moderation of the prices prior to official publication and also one should note that most often, there is very huge time span between audited and unaudited financial reports that if the sensitivity of the investor toward financial leverage is considered, it is not unusual to be able to moderate the prices in a response to this aspect during such a time span.

10. Conclusion and Suggestions

The overall results related to the current research which was conducted in two cross sectional and total years methods demonstrates that there is a weak relationship between the leverage (ratio of the long-term to long term assets) and liquidity rank. The other variables (price spread, stock depth and the Turnover Rate of Stock) did not show any significant relations. The leveraged companies showed higher liquidity rank (better rank) in comparison with the non-leveraged ones. With regard to this, the results of the current research corresponds with researches such as Simon (1996), W Butler, Groloun and Weston (2002), Mortal and L.Lipson (2003), Adryan and Shang shin(2008) , who have achieved a positive relation between leverage and liquidation. These results show that both the leverage and capital structure are considered as a related factor (even if they are weak ones) in decision-making trends of investors and shareholders and actually the investors take the risk of cash flows resulting from debt into account while taking decisions with their own parameters and principles.

Suggestions made out of research result:

- Informational asymmetry is one of the main reasons for the price spread and also the reduction of stocks liquidity at the market. The asymmetry results from lack of enough and prompt disclosure of information by the companies. If all the audited accounting information is presented in due course can have informational content and can involve in the process of pricing. Therefore, it is recommended to the Stock Exchange Organization to take more measures regarding establishment of necessary rules and regulations in order to maintain enough disclosure and information equilibrium and also due presentation of accounting and auditing information.

- One of the reasons behind the ambiguity of shareholders' reactions toward the distributed news can be the availability of restricting regulations such as base volume and the limitation of the economic fluctuation range. Such regulations adversely impact the natural trend of the market and the procedure of supply and demand. It is recommended to the Exchange organization to present appropriate approaches in order to assist in the completion of natural procedure of the market.

- Taking such various studies into account, the price spread and Stock Price Depth are considered as one of the significant and dependent tools of measuring liquidity of stocks. It is recommended that the Securities Exchange inserts the difference of prices of the suggested traded transaction accompanied by liquidity rank being used by investors, analysts and researches in its publicized reports by providing all required facilities.

- Considering the role of quality of disclosure played in liquidating the stocks of the companies, it is recommended to the managers to disclose complete information for investigators and in this way, reduce the informational asymmetry in the market and lower the indirect costs by increasing liquidity of stocks.

- By considering the effect of debt on the cash flows and risk and the company value and also since there are stockholders having extra payments in the companies, it is recommended to the stockholders and investors to pay attention to the balance sheet information and financial leverage of the companies while taking some investment decisions.

Abstract: Patient safety and the prevention of medical errors have become the focus of most healthcare providers. This study aimed to determine intervening variables of human errors in Iranian public hospitals. The data were collected via researcher-made questionnaire with the reliability coefficient 0.98. The questionnaire was scored by five point Likert Scale. Rotation method of Varimax with Kaiser Normalization was used via Factor analysis. The results of the study showed factor of healthcare provider explained 7.81 percent of total variance. It had twelve intervening variables affect medical errors in Iranian public hospitals. The most factor loadings (0.718) was related "Inadequate ability of healthcare provider to decision making accurately and timely" and the Least factor loadings (0.53) was related "Inadequate awareness/consciousness of health care providers (consume alcohol, Drowsiness)". The findings of this study revealed the systemic approach must be replaced in hospitals setting to ensure the provision of patient safety and showed the most important causes for the avoidance of the culture of blame.

Keywords: Human Errors, Hospital, Intervening Variables.

1. Introduction

The larger numbers of patients are seriously harmed as a result of adverse events despite the best intentions of dedicated, hard-working health-care providers. One of the most commonly cited causes of medical errors and adverse events is human error (Busse and Johnson, 1999; Cooper et al., 1978; Leape, 1994; Pelletier, 2001; Wilson et al., 1995; Kathleen L, 2006). Human error is routinely blamed for accidents in the air, on the railways, in complex surgery and in healthcare generally. (cook, Woods and Miller, 1998). When an error or adverse event occurred in a hospital setting, the most common reaction was to blame a person (Woodhouse et al., 2004; cook, Woods and Miller, 1998). However, most error eventually passes through the hands of a care provider. Even when the primary cause of harm is system failure, there is usually a human standing at the bedside. The human factor of medical error is the most tangible, the most visible, and the most disturbing (cosby, 2003). Healthcare services are also human activity systems (Behara and Valentine, 2001). The delivery of safe, high-quality health care has always been a goal of physicians, nurses and other health-care professionals. Indeed, students in medical and nursing schools have long been taught Florence Nightingale's dictum (also attributed, with some

debate, to Hippocrates, or the Hippocratic Oath): "first, do no harm" (Nightingale , 1863). Patient safety teaching needs to convey an understanding of the causes of adverse events and help develop skills to deal with error in healthcare settings. Graduates need to know how to reduce the occurrence of errors and also what to do when they make errors, when they witness an error or when they are told that someone else has made an error (patey et al.; 2007). The level of attention paid to the problem of medical errors has accelerated markedly in recent years, with research and discussion leading to a number of improvement initiatives in both the public and private sectors. Many physicians, nurses, pharmacists, rehabilitation therapists, and other types of health care providers may carry out these activities. Each provider has a vital role in patient care. Thus, the hospital has the highest level of accountability to ensure that each of these practitioners is qualified to provide safe and effective care and treatment to patients. So recognize the intervening variables of healthcare provider errors are a necessary step toward improving patient safety and reducing medical errors. The aim of this study was to identify the Intervening Variables of Human Errors in Iranian Public Hospitals.

2. Methods

This research was done in 2009-2010. Population included 684 process owners (12-person teams) in 57 public university hospitals of Tehran province (N = 684) including (24 non-teaching hospitals and 33 teaching hospitals) were active. The sample size was 396 persons selected by classified random sampling. The data were collected by a self-made questionnaire. Items to be included in the questionnaire were identified from literature review, focus group discussion, to ensure cultural adaptability of the literature in the Iranian healthcare setting. Focus group discussion was held in public hospitals, involving doctors, nurses, allied health staff and managers. Focus group discussion was prompted using items from the literature about patient safety. Content validity and construct validity were assured with expert judgment. The questionnaire was pilot tested for clarity on 36 process owners who were physicians, nurses and have experience of executive management. Analysis of the pilot data led to minor changes in the final survey instrument. Changes included modified wording of several questions to improve clarity as the removal of questions to maximize the internal consistency of the instrument. The reliability of the questionnaire was determined using Cronbach's alpha with the reliability coefficient 0.98. The constructs tested for internal consistency using Cronbach's alpha correlation. Correlations of the constructs were high, ranging from $r=0.81$ to $r=0.98$. The final questionnaire comprised 145 questions, which measured responses to one dependent variable, 7 demographic questions. Responses were scored 5 for extremely agree and one for extremely disagree.

The survey questionnaire was administered to 408 process owners in each of 34 public hospitals (There were 20 teaching hospitals and 14 non-teaching hospitals in the sample). Finally 398 questionnaires were completed.

The data were analyzed using SPSS Version 17. Exploratory factor analysis was used to determine the number and nature of factors describing the covariance structure of data.

3. Results

396 process owners' including 217 females and 179 males participated in this study. They all had a degree from B.S. through Ph.D. (170 B.S., 39 M.S., 71 M.D. and 116 Ph.D.). They had experience included (7% with a range of 1 to 5 yr, 14% with a range of 5 to 10 yr, 27% with a range of 10 to 15 yr, 28% with a range of 15 to 20 yr, 11% with a range of 20 to 25 yr, 13% with a range of 25 to 30 yr).

The result of KMO test for all the factors was 0.952, which is acceptable for factor analysis (Jae-On Kim, Mueller CW., 1985)

Table1. KMO and Bartlett's Testa

	Sig.	.000

a. Based on correlations

Table 2 illustrates process owner in Iranian public hospital only could identify 69.995% factors affecting medical errors. They believed that healthcare providers affect medical errors only 7.81% and the causes of 62.182% medical errors related to the other factors.

Table2. Total variance explained related to healthcare provider and the others factors

factor	Initial Eigen values		
	Total	% of variance	Cumulative%
healthcare provider	48.985	33.783	33.783
The others			36.212
Total			69.995
factor	Extraction Sums of Squared loadings		
	Total	% of variance	Cumulative%
healthcare provider	48.985	33.783	33.783
The others			36.212
Total			69.995
factor	Rotation Sums of Squared loadings		
	Total	% of variance	Cumulative%
healthcare provider	11.334	7.816	7.816
The others			62.182
Total			69.995

Twelve intervening variables as shown in figure1, whose factor loadings (absolute value) on this factor are relatively large among all the factors, are identified to interpret it. The priorities of key intervening variables considered.

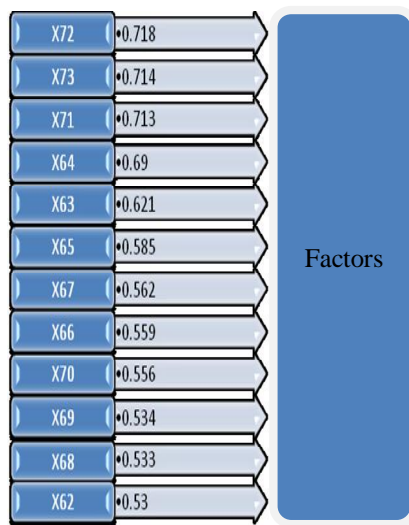

Figure1. Factor loadings (absolute value) on the factor of healthcare provider

The names and description of intervening variables affecting healthcare provider errors in Iranian public hospitals are:

- X72: Ability of healthcare provider to decision making accurately and timely
 X73: Effective patient assessment (correct diagnosis) with healthcare provider
 X71: Awareness of healthcare provider about potential risk point
 X64: Skills or the ability to act promptly and timely interventions of healthcare providers
 X63: Knowledge of healthcare provider
 X65: Experience of healthcare provider
 X67: Psychological characteristics of healthcare provider (e.g. concentration of thought, attention, and tranquility)
 X66: Physical characteristics of healthcare provider (fatigue, hunger, thirst, disease)
 X70: Ethical and legal responsibility and accountability of health care provider to its patients and community
 X69: Emotional barriers and motivations of healthcare provider
 X68: Healthcare provider use of consultation and specialists
 X62: Awareness/consciousness of health care providers (not to consume alcohol, not to work drowsily)

4. Discussion

Based on the results of the present research, the most significant intervening variables of human errors in Iranian public hospitals are 'Inadequate ability to decision making accurately and timely', 'Ineffective patient assessment (Incorrect diagnosis)', 'Inadequate awareness about potential risk point', 'Inadequate skill or ability to intervene promptly and timely', 'Inadequate knowledge', 'Inadequate experience', 'Psychological characteristics', 'Physical characteristics', 'Ethical and legal responsibility and accountability to patients and community', 'Emotional barriers and motivations', 'don't use of consultation and specialists', 'Inadequate awareness/consciousness'.

These finding are similar to the findings of the research titled "Work system design for patient safety: the SEIPS model" carried out by Carayon et al. in 2006. They showed that 'Education', 'skill', 'knowledge', 'Motivation and needs', 'Physical characteristics', 'Psychological characteristics' were elements of person component in their model.

The result of study done by West et al.(2009) about " Association of resident fatigue and distress with perceived medical errors" showed that among internal medicine residents, higher levels of fatigue and distress are independently associated with self-perceived medical errors. This paper had the similar results about physical characteristics such as fatigue and disease affect to human errors. Numerous reports have implicated fatigue and sleepiness as contributors to medical errors (Kohn, Corrigan, Donaldson; 1999, AHRQ; 2009, Lockley et al; 2007).

Helmreich and Musson(2003) in their research have found that lack of proficiency (training issue) or alertness(fatigue issue)are Individual (Physician) factors that increase probability of medical errors. Kumar and Steinbach used implementing the six sigma DMAIC cycle and developing cause-and-effect diagram in their research and showed that the causes of anesthesia errors were poorly trained people, poor anesthesia-related experience, poor familiarity with surgical procedure, poor familiarity anesthetic method, lack of skilled assistance or supervision, fatigue, haste, carelessness, negligence, restriction of visual field, emergency case, inadequate communication with team or laboratory personnel, methods. That paper had the similar results. It showed that preventable medical errors may occur because of doctors and nurses lack of experience. Consequently, a physician or nurse during their residency should not be allowed to be in charge of a task until he or she has assisted an experienced physician/nurse for a certain amount of time with that specific task. The number of training-on-the-job hours a hospital staff member has achieved should be

recorded. Before achieving the minimum amount of experience, a staff member should only be allowed to assist experienced staff. Medical errors caused by physician or nurse fatigue can be easily eliminated through the implementation of maximum working limits. In order to prevent medical errors that result from haste, understaffing must be resolved. There are cases, such as emergencies, where haste is inevitable. However, many situations where haste occurs can be prevented, since many errors resulting from haste have their source in understaffing. Therefore, quotas must be implemented that determine how many hospital staff members are required for a certain number of patients (Kumar and Steinbach, 2008).

Also Krueger (1994) has found substance abuse, and emotional distress can all adversely affect performance of health care provider.

In this study, clinical skills such as 'Inadequate ability to decision making accurately and timely', 'Ineffective patient assessment (Incorrect diagnosis)' are the highly loaded variables on factor of human error. Failures of judgment and decision making are led to the incorrect diagnosis.

Medical and other health information is essential for making correct decisions about which patient needs can be met by the health care organization; the efficient flow of services to the patient; and the appropriate transfer or discharge of the patient to his or her home or another care setting. This information may be in paper or electronic form or a combination of the two.

Diagnostic failures accounted for the majority of the adverse events in EDs reported by the Harvard Practice Study, and most were judged as negligent (leap; 1991). A number of authors have described the diagnostic process and where it can go wrong. (Graber, Gordon and Franklin ;2002, Kuhn;2002, Elstein and Schwarz ;2002, Kovacs and Croskerry ;1999).Diagnosis is always an interaction between the patient and the doctor or other professional, who are both influenced by the system in which they work (Vincent, 2006). Furthermore, a number of individual characteristics and the role they might play in terms of work practices that affect patient safety have been studied. The individual characteristics most likely to affect safety are low risk perception, sensation seeking, Type A behavior (aggressive, competitive and impatient), high self esteem, psychological ill health, and attitudes concerning safety (Firth-Cozens, Cording, Ginsburg, 2003). We cannot change the human condition, we can change the conditions under which humans work (reason, 2000).

So, we can control these intervening variables by corrective action to ameliorate deficiencies identified following competency testing.

Conclusion

In Iran healthcare provider is identified at the sharp end of errors but the individual is not the only cause. Multiple factors affect the patient safety. They may only affect care indirectly. For the provision of patient safety requires spreading systematic approach. This approach helps to identify other factors affecting medical errors and lead to develop comprehensive and systematic management based on safety and quality. This approach leads to proactive rather than reactive risk management. Developing this approach need to attract the participation of all stakeholders. To reduce medical errors the hospital must constantly evaluate (measure) its performance and use that information to identify ways in which it can improve. This self-evaluation must be planned and ongoing and should focus on systems and processes, not solely on individual performance. To be successful, the hospital leadership must ensure that the climate does not allow focus on "who is to blame." Appropriate educating for healthcare provider such as national and international conferences; ongoing professional education and development; Training of staff can help.

Acknowledgement

The authors thank the Process owners in selected public hospitals for their helpful comments and assistance with this work.

Carbon sequestration potential of Eucalyptus and Acacia plantation in central areas of Iran

Seyed Armin Hashemi¹

¹Department of Forestry, Lahijan Branch, Islamic Azad University, Lahijan, Iran.
hashemi@liau.ac.ir

Abstract: Carbon sequestration potential of *Eucalyptus camaldulensis* Dehnh and *Acacia salicina* Lindl planted in 1980 was studied at the age of 30 years in the elevation plain areas of Iran. Two station of this plantation in province were selected the sample plots and the diameter at breast height of all trees was measured. At least, there trees from each diameter class were randomly selected and cut and different parts of the trees including, trunks, branches and leaves were separately weighed. The main roots of one tree from each diameter class were also nine collected and weighed. To estimate the man weight of litter per hectare, 40 sample plots of one square meter were randomly chosen and the amount of litter was determined. The percent of organic carbon in leaves and litter was also calculated in the laboratory. The amount of carbon sequestered in the soil of plantation area was calculated and compared with control. This study showed that the amount of carbon sequestered by *E.camaldulensis* in the productive site and poor site was about 8.2 and 1.73 ton ha⁻¹year⁻¹, respectively. On the other hand, for *Acacia salicina* in the poor site of this figure was 2.1 ton/ha in year. The highest the amount of sequestered carbon in *E.camaldulensis* was in 30 centimeter diameter class. This figure for *Acacia* was in 25 centimeter diameter class. The amount of carbon sequestered in different parts of the tree showed a significant difference at 0.01 also in *E.camaldulensis*, there was a significant difference in the amount of carbon sequestration between the suitable and poor sites. This study showed that there is a great potential of plantations in Fars province and similar areas of the country. This plantation will maintain suitable green areas and belts and produce wood materials for consumption in several ways. Forever planting trees will lead to the reduction of CO₂ in atmosphere which reduces the greenhouse effect, a program which is university promoted and partially sponsored by united nations and some industrialized countries.

Key words: Carbon sequestration, plantation, *Eucalyptus camaldulensis* Dehnh, *Acacia salicina* Lindl., Iran

1.Introduction

Researchers generally believe that the main factor of increasing the temperature of earth is CO₂ (Korner *etal.*,2003). From the time of beginning industrial revolution in 19th century, the viscosity of carbon dioxide in atmosphere has reached from 280 to 365 section in million and its considered that in 21th century it would be reached to 600 section in million which this cause increasing medium annual temperature of the earth at the rate of 1C° to 4C°(Korner *etal.*,2003).However main part of carbon is holed by oceans and is kept as reserves, but studies show that the source of oceans are not so big that can reserve additional carbon in themselves and its residue should be reserved in land (Kenneth *etal.*, 2000). The main resources for reserving carbon are plants particularly forests. Forest ecosystems of the world in case of activity in order to reserve carbon, can hold about 2.3 gig ton carbon annually(Thompson *etal.*,1989). It's estimated that average rate of distributed CO₂ from fossil fuels and change of the use of farms during 1980 by now is about 7.6 milliard ton in a year(Dixon *etal.*,1994). Refining carbon by artificial methods such as filtration and etc include a lot of charges so that this

expense in America has been measured about 100 to 300 \$ for each ton carbon (Finer,1996). In this direction, industrial countries, have predicated prolonged programs in order to decrease the viscosity of carbon dioxide that in Kyoto conference, this problem was pronounced seriously and countries were obliged to reserve carbon by using particularly natural and artificial forests.

In this case of using plants and planting trees in the form of plantation we can not only create green place and produce wood or use other benefits of forest, but also can obtain the aim of reserving carbon. In most countries, considerable researches have been done for measuring the potential of fixing carbon and different methods for doing this in natural and planting forests and its continuing (Cannel *etal.*,1992 ;Dixon *etal.*,1994).

By accessed to the potential of reserving carbon in plantations of eucalyptus and acacia planted in this area, it will be provided a good background for developing plantation.

2. Materials and Methods

This study has been done in growing places of basin 21 from dividing the auriferous basins of center area of country .With due attention to ambrotermic curve of beginning and end moisture period is 20 Nov. and 15 Feb. respectively. Minimal absolute temperature is -2 C° and maximum temperature is 45 C°. There are two research stations of adaptation tests of different eucalyptus and acacia species have placed in the area of planting place were considered as sample plots.

Sample plots

For species eucalyptus according to adaptation of this species in all conditions of planting place , sample plots were selected in two planting place of weak and relatively fertile and *A.Salicina* due to the lack of planting in different planting place , forcefully was selected in a planting place of sample plots.

Measurement of biomass

In other to determine the situation of planted mass in selected sample plots from diameter at breast to accuracy of centimeter were measured hundred per cent , and all aggregated statistics were analyzed by using the soft wares Minitab and Excel and drawing the curve of number in diameter classes and height was done. According to the dispersion of number in diameter classes of existing trees , in each mass , minimal 3 trees from each diameter class were selected randomly within existing trees and marked with dye and after the cutting of different organs , were weighed with accuracy of gram. In order to estimate the existing litter under trees, 40 sample plots of one square meter under sample trees were chosen and existing litter were weighed with accuracy of gram. From each diameter class, one sample selected and all roots with the diameter more than 1mm were collected until the depth of 2 meter and were weighed. After generalizing obtained numbers to all existing trees, the weight of existing biomass weighed in each sample plots.

Determining conversion coefficient

From different organs of trees and litters of different mass, three samples delivered to laboratory and then in order to samples were placed into kiln after completely conversion to ash, these . These samples were weighed again. By determining the weight of ash and having initial weight and the ratio of organic carbon to organic materials, the amounts of organic carbon in each tree organs were calculated separately. Finally by having initial weight and percentage of organic carbon for each organ separately, conversion coefficient was calculated.

3. Results

Results of measuring different organs

The results of statistical analysis at the basis organs of cutter sample trees in the station number one as relatively fertile planting place and the station number two as a weak planting place have been presented in terms of ton in hectare in year in table 1. A: Eucalyptus relatively fertile growing place, B: Eucalyptus weak growing place.

Table 1 – Results about the production of biomass in different aerial organ in ton in hectare in year

aerial organ	total	Weight of litter	weight of root	Wet weight of leaf	Wet weight of lops	Wet weight of trunk
A	15.906	1.578	3.050	0.406	1.562	13.938
B	3.813	0.268	0.284	0.156	0.483	3.813
Acacia	3.981	0.205	0.066	0.146	0.508	3.327

E.Camaldulensis	28.4	24.5	21.34	52.7	46.65
A.Salicia	34.25	28.59	16.85	53.36	47.99

Table 3-percent rates of organic carbon in different growing places (%)

Species	Growing place		Soil depth
	Weak	Relatively	
E.Camaldulensis	0.321	6.709	0-30
A.Salicia	0.175	-	0-30

Results of determining conversion coefficient of biomass to organic carbon

The results of the experiments about determination of conversion coefficient of wet weight of different organs of tree species to organic carbon in this project have been shown in table 2.It is necessary to note that between the obtained numbers for repeating the samples, meaningful difference was not observed.

Results of determining the amounts of reserved carbon in soil (*E. camaldulensis*)

By doing the experiment, of determining the amounts of organic carbon of harvested soil from different planting place and comparing with control

samples, the amounts of percentage of organic carbon in different growing places have been presented in table 3.

Results of the amounts of annual carbon sequestration

The results from the measurements and generalization of conversion coefficient in the region of the project at the basis of ton in hectare in year have been presented in table 4.

Table 4 the amounts of carbon sequestration (ton) in different parts of studied species

species	total	soil	litter	Root	leaf	lops	trunk
A	8.407	0.353	0.836	1.710	0.97	0.483	4.158
B	1.734	0.119	0.228	0.132	0.111	0.143	1.001
Acacia	2.1019	0.20	0.104	0.109	0.104	0.245	1.239

A: Eucalyptus relatively fertile growing place ,B: Eucalyptus weak growing place

Statistical analysis of *E. camaldulensis* in fertile growing place

The results from comparing between average carbon sequestrations in different organs of *E.camaldulensis* in this growing place shows that there is a meaningful percentage of difference between carbon sequestrations in different organs at level 1%. According to Danken test, the average amounts of carbon sequestration in different organs are placed in three classes. Average weight of sequestrated carbon in trunk with 164 kg is maximum rate and is placed in class A and sequestrated carbon in root with 75 kg is placed in class B and the weight of carbon in lops and leaf don't have any difference in one percent together and are placed in class C. The details of statistical analysis have been presented in tables 5 and table6.

The weight of carbon in trunk	A	29.4671
The weight of carbon in trunk	b	3.8846
The weight of carbon in leaf	C	1.0941
The weight of carbon in root	B	4.8933

Weak growing place

The results of comparing between the average carbon sequestrations in different organs of *E.camaldulensis* in this growing place shows that there is a meaningful percentage of difference between carbon sequestrations in different organs at level 1%. According to Danken test, average amounts of carbon sequestration in different organs are placed in three classes.

Average weight of sequestration carbon in trunk with 30.34is maximum rate and is placed in class A and sequestrated carbon in lops and root is placed in class B and don't have meaningful difference together in level 1 percent. Average weight of carbon in leaf with 1.1 is placed in class C. The details of statistical analysis have been presented in table 7 and table 8.

The species *A. Salicina*

The table of variance analysis between the weights of sequestrated carbon in different organs of *A. Salicina* planted in the region show that there is a difference at the level of 1 percent between the weights of different organs. According to Danken test , average amounts of carbon sequestration of different organs are placed in 3 class. Average weight of sequestrated carbon in trunk with 45.9 is maximum rate and is placed in class A and sequestrated carbon in lops with 6.3 is placed in class B and with the weight of root. At level 1, it doesn't have meaningful percentage of difference. Average weight of the carbon in leaf with 1.579 is placed in class C. Average weight of sequestrated carbon in root with 4.34 is placed in class B C and doesn't show a meaningful percentage of difference at level 1% with leaf and lops. The details of statistical analysis have been presented in tables 9 and table 10.

Discussion

The results of this research showed that species *Eucalyptus camaldulensis* Dehnh and *Acacia Salicina* Lind I can thoroughly located in rigid regions and play an efficient role in relation to carbon sequestration. Analyzing collected information and statistics in relation to studied species in this research show that *E.Camaldulensis* in the station which due to suitable depth of soil and coming up of underground waters , is as a relatively fertile growing place which after so years could produce the amounts of 20.534 ton biomass that by considering the litter poured under trees and the amounts of carbon added to soil as compared with control region could reserve

the amount of 8.2 ton organic carbon in hectare in year.

In the station due to stony soil and coming down of underground waters , as a result of lower fertility as compared with the station as a weak growing place, planted eucalypts has relatively weak growing condition so that after 30 years could produce amounts of 4.4 ton biomass. By considering the litter and existing carbon in soil , these samples have reserved totally 1.1 ton organic carbon in hectare in year. The acacia, after 30 years could produce amounts of 4.253 ton biomass. By considering the litter and existing carbon in soil, totally these samples have reserved 1.5019 ton organic carbon in hectare in year.

From the view of the share of each organs in carbon sequestration 50% of the production of biomass has been allocated to trunk wood that in this research in eucalyptus in both growing place is also close to 50 but acacia biomass with 75% relative to announced numbers in references , has meaningful difference which is considered that the reason being the decrease of the production of leaf , root and lops , like wise being pure in mass and being low the plants under floor can be also major reasons(Watson *etal.*,2000) . The amounts of sequestrated carbon by soil of two studied species in eucalyptus biomass are 0.227 and 0.131 ton in hectare in year respectively and in acacia biomass is 0.90 ton in hectare in year which there is a meaningful difference in comparing between two species. In relation to high difference between the amounts of sequestrated carbon in soil, of acacia and eucalyptus and being low in it , it seems that the availability of higher nitrogen in under floor soil of acacia as a result of high speed in mineralizing organic carbon cause the amounts of sequestered carbon relative to available soil under floor of eucalyptus be low. In relation to the amounts of produced litter under floor of studied species, it seems that according to the ability of fertility in studied growing place and species combination of studied biomass, acceptable rates have been estimated.

The amounts of produces litter depends on major factors like type of species , climate , fertility of growing place and ability of production so that for different species in different growing places , different numbers have been presented(Watson *etal.*,2000).

In relation to obtained coefficients in order to convert wet weight of biomass to carbon at the basis of previous researches , conversion coefficient was considered 21% for needle – leaf trees and 24% for wide – leaf trees (Thompson *etal.*,1989). Also in another research , total conversion coefficient of the weight of dry wood to carbon has been considered

50% and certain weight of needle – leaf trees has been estimated 350 kg /m³ and for wide – leaf trees 550 kg/ m³ (Kilbride *etal.*,1999).

In this study also at the basis of measurements, different numbers were obtained for different organs. Table 2 which minimum percentage is related to leaves and maximum percentage is related to roots which is seems that the decrease of conversion coefficient in leaves is due to the amounts of minerals in leaves are high. The reason that conversion coefficient is high in acacia is probably low amounts of water in roots. Generally , conversion coefficient of produced biomass in all above organs and underground of eucalyptus has been calculated 34% and for acacia this amounts are 35.6% which is more than announced average in references.

By considering aerial organs singly, conversion coefficient for eucalyptus is 27.6% and for acacia is 30.7 which it seems that the reason of its increase rather than announced rates, in references, is dryness of studied regions and being low of moisture of produced organs (Finer ,1996).

In relation to the amounts of root production , we should say that because of good permeability of soil in studied area , the volume of produced root specially in eucalyptus is very well which according to the limit of studied depth with considering available roots in lower depth , the volume of real production of root is more than calculated numbers. In relation to the amounts of total carbon sequestration in different forest masses, we should say that there is a direct relationship between sequestered carbon with the type of species, fertility of growing place, cultivating operations and forestology which is done during life period of trees (Dewar *etal.*,1992). In the studied region because of the lack of doing cultivating operations in planted biomass and near distance of trees, we can increase the growing of trees.

Generally , according to complex subjects in natural ecosystems and problems such as mineralizing organic materials , impact of climatic factors and other factors on absorption of CO₂ in trees , wider researches in this era seems necessary .

Abstract: The present study aimed to investigate the impact of educational program among open heart surgery patients on minimizing the incidence of post operative infections. Data were collected from cardiothoracic surgery department, intensive care unit, and outpatient clinic at Assiut University Hospital. The study was conducted on 60 adult patients with open heart surgery (30 - study group and 30 - control group) who have been selected randomly. Data were collected through: four tools; (cardiac surgery patient needs assessment sheet, cardiac teaching program based on individualized patient needs assessment, cardiac post operative observation checklist sheet, and cardiac post operative wound site infection evaluation sheet). Results of this study concluded that, more than half of the patients in study group 53.3 % were females, 70 % were married, and 40 % their ages ranged from 18 - 29 years. While the majority of the patients in the control group 63.3 % were male, 46.7 % were married, and 33.3 % from 30 - 39 years. Conclusion; Significant differences for improvements throughout educational program phases among study group regarding total score of knowledge and practice about open heart surgery. The study recommended that, pamphlets and simple illustration booklet should be available for patients illiterate to with simple explain how to safely live after open heart surgery. The patients must understand the importance of oral hygiene and visiting a dentist regularly because dental infections can affect the valve prosthetic.

Key Words: Educational Program; Heart Surgery; Patient Post Operative Infection

1. Introduction:

Cardiac surgery is surgery on the heart and/or great vessels performed by a cardiac surgeon. Frequently, it is done to treat ischemic heart disease (for example, coronary artery bypass grafting), correct congenital heart disease, or treat valvular heart disease created by different causes including endocarditis. It also includes heart transplantation (<http://en.wikipedia.org>, 2007).

Postoperative surgical site infections (SSIs) are a major source of morbidity in the United States. Wound infections rates are; clean surgery infection rate typically 1-2 %, clean-contaminated infection rate usually < 10 %, contaminated infection rate 15-20 %, and dirty infection rate 40% (<http://www.worldwidewounds.com/2005>).

Nurses play a vital role in the prevention of SSIs in patients with open heart surgery. By managing disease processes, through education and assessment (Harrington *et al.*, 2005). The unique challenge for the critical care nurse is to integrate theoretical knowledge, assessment skills, and problem solving ability to provide optimal nursing care and maintain high quality outcomes (Morton & Fontaine, 2009).

Pre operative preparation for cardiac surgery includes physiological and psychological components. Physiological preparation includes history, physical examination, chest radiography, and an ECG. Effective pre operative teaching, which reduces anxiety and physiological responses to stress and after surgery, is an important aspect of psychological preparation. The surgical procedure, the Intraoperative, and postoperative experiences are explained to the patient (Morton & Fontaine, 2009).

Post operative phase patients are transported directly to the intensive care unit (ICU), where they recover from anesthesia and usually remain for 24 hours after surgery. Patients arrive in the ICU with numerous lines and tubes (e.g., endotracheal tube and hemodynamic monitoring lines). Immediate postoperative care involves cardiac monitoring and maintenance of oxygenation and hemodynamic stability (Rosborough, 2006).

Discharge instructions for heart surgery patients includes observe appetite of the patient, signs and symptoms of swelling, sleeping condition, gastro intestinal problems as constipation, diet, care of incision, instruction about medication used, activity, shower daily if he/she is strong enough to stand and wash the incision with a mild antimicrobial soap. Using a clean towel, the patient should pat dry the

incision. No lotions, creams, oils, or powders are to be used. The patient also should avoid sun exposure, sexual, driving, lifting heavy objects, work, stress management and follow exercise program given to the patient by physical therapist in the hospital (Society of Thoracic Surgeons, 2006).

Significance of the study:

Wound site infections are a major source of post operative complications, accounting for approximately a quarter of all nosocomial infections. Many international studies have defined the patients at highest risk for infection in general and in specific operative procedures (Abd El Aziz *et al.*, 2007). However, there is a scarcity of local studies dealing with this problem. It is hoped that, data generated from this study could help in educating the patient and managing care for patients with open heart surgery as well as training adequately the patients to decrease incidence of infection and complications. Complications increase morbidity, inpatient stay, hospital cost, and increase mortality of patients. So, this study will be carried out to investigate the impact of educational program among open heart surgery patients on minimizing the incidence of post operative infections.

Aim of the study:

To investigate the impact of educational program among open heart surgery patients on minimizing the incidence of post operative infections.

Research hypothesis:-

Open heart surgery patient attending educational program will exhibit a positive effect on minimizing surgical site infections post operatively.

Material and Methods:

Research design:

Quasi-experimental research design was utilized to fulfill the aim of this study.

Materials:-

Setting:-

Cardiothoracic surgery department, intensive care unit, and outpatient clinic for follow up at Assiut University Hospital.

Subjects:

Patients admitted in cardiothoracic surgery department (60 patients) were included in the study, (31) male and (29) female their ages ranged between 18 and 60 years. The patients classified inrolled randomly (convenience sample) into two groups (study and control group). The study group (30 patients) who were received nursing instruction (educational teaching nursing program), while the control group (30 patients) who were received routine hospital care.

Tools of the study:

Four tools were used to investigate the impact of educational program among open heart surgery

patients on minimizing the incidence of post operative infections. These tools were deduced by the researcher based on reviewing of related literatures (Horan & Gaynes, 2004; Williams & Wilkins, 2006; Smeltzer *et al.*, 2008; Berman *et al.*, 2009; Morton & Fontaine, 2009; Proehi, 2009).

Tool I:

Cardiac surgery patient needs assessment sheet (Annex 1):

This tool was developed to assess open heart surgery patients needs. It contains 23 items and will be developed by the researcher and it includes 5 parts:

Part I: Assessment of the sociodemographic patients' profile: To assess the patients profile as patient's name, age, sex, marital status, diagnosis, family size, housing condition...ect).

Part II: Patients nursing needs pre cardio surgery: This part includes structured items to identify patient's pre cardiac surgery nursing needs.

1. Present, Past, and family history

Scoring system:

$$\text{For body mass index (BMI)} = \frac{\text{Weight (kg)}}{\text{Height (in meters)}^2}$$

This equation and classification of BMI were adopted from (Davis and Sherer 2000; Syed *et al.*, 2000).

2. Physical examination.

3. Psychological needs: assess psychological state of patient such as fear, irritable, insomnia, and apprehensive.

Part III: Laboratory investigation.

Part V: Diagnostic procedure.

Part IV: This part carry out pre/ post test questionnaire and observation checklist sheet was used prior to implementation of the teaching program to measure the exact knowledge level and assessment practice for patient about open heart surgery. The same part used after implementation of the teaching program and after 2 weeks later to evaluate the gain in knowledge after the intervention. It consists of 2 main parts: Patient assessment knowledge and practice about open heart surgery.

Scoring system:

As regard patient assessment knowledge about open heart surgery which includes 18 items, each item was assessed, categorized, and scored into either yes = 1 or no = 0 on all items. Patient assessment practice about open heart surgery. Which includes 14 items, each item was observed, categorized, and scored into either yes = 1 or no = 0 on all items.

Tool II:

Cardiac teaching program based on individualized patient needs assessment (Annex2)

The educational program was designed to minimizing the incidence of post operative infections

with open heart surgery patients through individualized session of educational program. It developed by the researcher based on the review of relevant literature, available resources, and the patient needs assessment. Number of session; a total 9 educational sessions will be conducted for each patient in addition to the pre assessment session. Preparing of educational training place, teaching aid and media (pictures, Arabic handout; the content of program modified in Arabic language and give it to the patient, and models) to help and facilitate the implementation of the educational program for the patient. Prepare the contents of training program, based on the assessment and the available equipment in the unit for its application.

The first session; included information about the heart and its function, meaning of heart disease.

The second session; provided information about open heart surgery and importance of surgery.

The third session; included information about teaching skills related to preparation before surgery.

The fourth session; included information about daily activity and exercises.

The fifth session and sixth session; included information about wound care schedules.

The seventh session; included information about specific nutrition for post cardiothoracic surgery.

The eighth sessions; included information about wound infection: local and systemic signs and symptoms, and medication used.

The ninth session; included information about discharge instructions for heart surgery patients. The duration of each session about 15 – 20 minutes according to patient tolerance. The end of each session makes discussion and feedback, except for the session for discharge instruction, which take 60 minutes

Tool III:

Cardiac post operative observation check list sheet (Annex 3):

An observation checklist was designed based on reviewed related literature Serna & Cathy (2006); Bonnie & Barnard (2007). The observation was performed to evaluation of effectiveness of the educational nursing program related to postoperative wound management on minimizing infection before discharge and follow up post discharge.

As regard cardiac post operative observation check list sheet, each item was observed, categorized, and scored into either present or not present on all items of local wound manifestation of infection and systemic manifestation schedule of observations.

Tool V: Cardiac post operative wound site infection evaluation sheet:

Used evaluation tool sheet for wound site infection (Southampton Wound Assessment Scale) The

wounds were graded before discharge and after 10 – 14 days postoperatively into one of four categories; normal healing, minor complication, wound infection , and major haematoma (Pudner, 2005).

Southampton scoring system:

Grade	Appearance
0	Normal healing
1. Normal healing with mild bruising or erythema: A B C	Some bruising Considerable bruising Mild erythemia
2. Erythema plus others signs of inflammation: A B C D	At one point Around suture Along wound Around wound
3. Clear or haemoserous discharge: A B C D	At one point only (< 2 cm) Along wound (> 2 cm) Large Volume Prolonged (> 3 days)
4. Major complication (Pus): 0 A B	Normal At one point (< 2 cm) Along wound (>2cm)
5. Deep or severe wound infection with or without tissue breakdown; haematoma requiring aspiration	

Scoring system:

As regard cardiac post operative wound site infection evaluation sheet, each item was observed, categorized, and scored into either present or not present on all items of Southampton scoring system for study and control groups.

2. Methods:-

Techniques for data collection:

- Official approval and administration permission were obtained from the head of internal cardiothoracic surgery department and post operative ICU to collect the necessary data.
- The consent from the patients who will be participating in the study will be taken.

1. The tools 1, 2, 3 and 4 used in this study was developed by the researcher based on reviewing the relevant literature (Bonnie & Barnard, 2007).

2. Jury of programs tested by 5 expertise's from the field of staff thoracic surgery and nursing educators for content validity of program.

- A pilot study was conducted during September 2009. It included 5 patients, in order to test the clarity and applicability of the tools.

- The data collection covered a period of one year starting from October 2009 till the end of October 2010.

3. Confidentiality and anonymity were assured.

Description of the nursing intervention program:

This program included three major parts;

1- The first was concerning the cognitive skills, i.e. knowledge about; The heart and its function, meaning of heart disease, definition and indications of open heart surgery, wound care schedules, knowledge about preoperative preparation, and postoperative instructions as regards open heart surgery, information about specific nutrition for post cardiac surgery, wound infection; local and systemic signs and symptoms, and medication used and discharge instructions for post cardiac surgery patients, and the importance of follow-up instruction of care.

2- The second was concerning the practical skills, i.e. deep breathing and coughing exercise, leg exercise, activities of daily living.

3- The third was related to carry out (implementation) the educational program practice among open heart surgery patients on minimizing the incidence of post operative infections.

Procedure:

The study was carried out in three phases: 1st, 2nd and 3rd phases:

1- Preparatory phase (Assessment and planning phase), involved the following: Review of relevant literature (Berman *et al.*, 2009), (nursing textbooks, journals, internet resources, etc), about nursing care for cardiac patient, jury for program by 9 expertise nurses and doctors, arrange for the training program schedule, based on the contents of the program, each patient was interviewed and counseled individually, time availability and the resources available.

2-The second phase (implementation phase): This phase comprised the preoperative, postoperative, and during this phase the exercise training program was implemented.

Pre-operatively:

- Patients were equally enrolled in the study as control and study groups sequentially. The 1st patient's interview was used to explain purpose and nature of the study as well as patient agreement for voluntary participation was obtained.

- The 1st 3 sessions from educational nursing program were carry out in 2nd interview with study group and take break 10 minutes between every session.

- The 4th, 5th, and 6th sessions from educational nursing program were carry out in 3rd interview with study group and take break 10 minutes between every session.

- The last 3 sessions from educational nursing program only were carry out in 4th interview with study group and take break 5 minutes between every session.

Postoperatively:

- The 5th interview with study group was at 1st day post-operatively, and then once time daily during hospitalization for base line data was obtained from study and control groups patients to fill tool 3.

- Before discharge the investigator emphasized the importance of follow up visit for all subjects (study and control) and arranged with study group the time and place for follow up which were 2 weeks postoperatively in out patient cardio thoracic surgery clinic at Assiut University Hospitals.

3-The last phase of proposed teaching program is the evaluation phase. After implementation as well as after 2 weeks the patient knowledge and practices has been evaluated by the researcher through filling the tool (1). Also local wound and systemic manifestation of infection was assessed utilizing tool 3 during hospitalization before discharge and after 2 weeks post discharge (follow up). A line of contact was established between the investigator and subjects of both groups for feed back, monitoring, and provision of needed consultation and help.

Analysis of data

Data collected by computer program SPSS" version. 17" Chicago. USA. Data expressed as "mean \pm standard deviation" "number, percentage". Using T.test to determine significant for numeric variable. Using Chi.squire test to determine significant for non-parametric variable. Using person's correlation for numeric variable in the same group.

n.s P > 0.05 no significant.

P < 0.05 significant.

** P < 0.01 moderate significant.

*** P < 0.001 highly significant.

Limitations of study:

1- Time available for follow up not enough as many patients were coming from far town and need to leave hospital early.

2- The patient's anxiety and feelings of vulnerability may interfere with the ability to learn information provided.

3- Participants suffered from transportation and financial problems.

3. Results:

Distribution of the biosociodemographic variables in study and control group subjects: the data reveals the more than half of the patients' in study group 53.3 % was female, 70 % were married, were 40 % from (18 to 29 years), 33.3 % were illiterate, 50 % were non working, family size 70 % from 4 to 8 persons and 56.7 % were moderate housing condition.. While the patients' in control group 63.3 % were male, 46.7 % were married, were 33.4 % from (30 to 39 years), 26.7 % were read & write, 43.3 % were non working, family size 66.7 % from 4 to 8 persons and 46.7 % were low housing condition. With no statistical significant difference between study and control groups as regards biosociodemographic variables.

Distribution of the sample according to vital signs means scores preoperative assessment for both study and control groups: There are highest mean scores as regard to temperature and pulse rate in control group than in study group (37.04 ± 0.37 , 36.92 ± 0.457 and 85.53 ± 15.38 , 83.43 ± 11.55 , respectively). Table show that highly statistical difference between control and study group related to respiratory rate ($P = 0.005$).

Distribution of the sample according to preoperative risk factors for study and control group: the high percentage in both study and control groups (80 % and 73.3 %, respectively) have non smoking. As regards body mass index the highest percentage (63.3 % and 40%, respectively) in study and control groups have standard level of weight. As regard percentage of chronic obstructive pulmonary disease and use of antibiotics they were equally in both groups, while highest percentage in study group have used of anticoagulant (80%) and one third of patients in control group have hypertension (33.3 %).

Distribution of the sample according to hereditary diseases & medical history for both study and control group: more than half percentage (60 %) in study group have diabetes and 40 % have hypertension and in control group were 80 % of patients have diabetes and 76.7 % hypertension. As regard the medical history streptococcal infections it was found that 86.7 % and 96.7 % in study and control groups, respectively. There was significant difference related to hypertension between both groups.

Table (1): This table shows that the cardiovascular preoperative and health habits clinical assessment for both study and control groups. The findings indicated that 96.7 % and 100 % of the patients in the study and control groups had palpitation preoperatively, while half of the sample in both study group and control had equal percent of leg edema. Concerning of extremity pain of both study and control groups

preoperative assessment; the findings indicated that there were significant differences between the study and control groups in preoperative period ($p < 0.05$).

The data reveals that cigarette smoking the majority of the patients' in study group had smoked cigarette more than control ones (83.3 %, 62.5 % respectively). The result also revealed that, there were highest mean scores of smoking index was found in study group than control ones (310 ± 65.21 , 120.23 ± 20.25 , respectively). The data reveals that the patients' in control group as performing exercise more than study ones (33.3 %, 26.7 % respectively). Difference was statistically significant ($p < 0.01$) for smoking index, and common symptom.

Table (2): This table demonstrates that significant difference was found between study and control groups as regard magnesium studies finding ($P = 0.042$).

Table (3): This table demonstrates that, significant difference was found between study and control groups as regard coagulation factories and blood glucose studies.

Table (4): The highest percentage (33.33 and 26.67 %) in study group and in control groups were has knowledge about rest and sleep. As regards percentage of knowledge about define of surgical site infection, sources and predisposing factors for surgical site infection, health teaching activities after discharge, notify the physician if patient have any abnormal, and daily activities to infection control they are equally in both groups and they have not any knowledge about this items.

Table (5): As regards pre operative nursing care practice the highest percentage (73.33 % and 66.67 %) in study and in control groups were have about foot and leg exercises, while they have not any knowledge about how to use incentive spirometry and elastic stocking. Also the table shows that assessment of level of practice about post operative nursing care among patients in study and control group, approximately an equal percentage in study and control groups (73.33 % and 70 %) were have knowledge about nursing care of urinary catheter, activities and exercises in intensive care unit. As regards discharge instructions for open heart surgery patients the highest percentage (60 % and 43.33 %) for study and control groups have had knowledge about how perform walking exercises.

Table (6): The above table shows that, there were significant differences improvements throughout the educational program phases among study group regarding total score of knowledge and practice with $P = 0.000$, 0.000 about open heart surgery.

Table (7): The above table shows that, there were statistical significant differences improvements of throughout the educational program phases among

study group while non statistical significant differences were noticed throughout the educational program phases among control group regarding level of knowledge and practice.

Table (8): This table shows that, Non significant difference were existed between infection scoring system at three phases for both group in all items except normal healing in pre discharge ($P = 0.06$). Also table enumerate that significant difference in post discharge for all items except major complication ($P = 0.015$), deep or severe wound infection ($P = 0.03^*$), and clear wound discharge ($P = 0.009$).

Table (9): This table demonstrates that, non significant difference between study and control groups as regard to hospital stay and ICU stay.

Figure (1): The table mentioned that, statistical significant differences of study groups was existed between housing condition & incidence of namely fever ($p=0.005$), delayed wound healing ($p=0.027$) and pneumonia ($p=0.027$).

Figure (2): The table shows that, statistical significant differences was existed for study group between ICU stay & incidence of fever, delayed wound healing, endocarditis, myocarditis, pericarditis and pneumonia.

Figure (3): The table mentioned that, a statistical significant difference was existed for study group between hospital stay & incidence of endocarditis, myocarditis, and pericarditis ($p < 0.01$).

Table (1): Distribution of the sample according to preoperative cardiovascular clinical assessment and health habits for study and control group.

4. Discussion:

Patient education is an essential component of nursing practice, there has been a continuous development and emphasize on the leadership role of nurses in the arena over the last century. Kane (2003) stated that the nurse is responsible for providing preoperative nursing care for patients which includes assessing physical and psychological needs preparing patients for operation includes the following instruction such as listing medication routinely, limitation of eating or drinking before surgery with specific time, bathing, checking vital signs, laboratory investigation and administrating preoperative medication.

Based on the results of the present study biosocio-demographic characteristics, two groups study & control were included in this study with no statistically significant differences shown between them regarding; sex, age, marital status, educational level, occupation, family size, and housing condition at the beginning of the study.

Concerning sex, the present study showed that approximately half of study and control groups were female, this result agree with Hopkins, (2005) study finding who mentioned that the majority of participated patients with open heart surgery were females. Whiles this disagrees with that of Stahle(1997) and Borger (1998) who reported that fewer female patients than males (female: male ratio = 1: 4.4).

The result revealed that, more than one third of the total studied patients were in the age group from 18 - 29 years old in study group and control group. On same line, this finding disagrees with Chih-Hung (2005) who reported that the number of open heart surgery is increasing in patient who are 50 years old or more.

The present study findings have shown that; one third of the study groups were illiterate and less than one third of the control group were able to read and write. As patient's education can increase the patients' awareness toward the surgery and the importance of follow up program.

The present study showed that, the mean scores vital signs in study group in preoperative phase were less than those of the control ones especially for temperature and pulse (85.53 ± 15.38 , 83.43 ± 11.55 and 37.04 ± 0.37 , 36.92 ± 0.457 respectively) with highly statistical difference between control and study group related to respiratory rate (0.005). Punder (2005) and Koplow and Hardin (2007) mentioned that pulse and blood pressure serve as useful tools to assess cardiac output in heart disease..

Based in the results in the present study preoperative cardiovascular clinical assessment, more than two third of study group and all patients who participate in control group have palpitation and

nocturnal dyspnea, these findings is at one with those of Gamer *et al.*(1996), Mangram *et al.*(1999), and Spelman *et al.* (2000) who reported that, all patients with cardiac disease have complained with palpitation and nocturnal dyspnea.

The present study showed that, consumption of tea and coffee it was more prevalent among control group subjects than those in the study ones. More than two third of study and control group were non smoker. This agrees with those of Kleinbaum *et al.*(1998), Delgado *et al.*(2001), and Kern (2005) who reported that, the majority of sample in study and control group were smokers and smoking is considered one of the risk factors for sternal surgical site infection.

According to Debacker *et al.*(2003) who recommended that physical activity for cardiac patient should be positively encouraged because this may reduce blood pressure, cholesterol level, and body weight. Patients should be encouraged to exercise at least four times a week, but preferably daily for a period of 30 minutes. Exercise does not need to be complex or competitive; a daily walk is sufficient to gain health benefits. These contradicts with study more than two third of the patients were not performing exercises (walking) in both groups. The American College Sports Medicine (ACSM, 1993) guidelines and Ellis (1995) who stressed that the individual will benefit from daily bouts of aerobic exercise totaling 30 minutes.

According to Syed and Davis (2000) who mentioned that within the standard level of weight 20 to < 26, over weight 26 to < 30, obese > 40 Kg. It was found in the present study, two third of the study and more than one third in the control group were having standard level of weight. According to Grady and Jalowiec (1995), Debacker *et al.*(2003) and Jarrick(2006) who recommended that nutritional information should be given to optimize wound healing, maintain ideal body weight and reduce cholesterol levels if elevated.

With regard associated disease, the study revealed that less than one third of subjects in study and control group were complaining from diabetes this may be due to that most of the sample were young (18 -29 years). Slaughter *et al.* (1993), Minohara *et al.*(1993), Spelman *et al.* (2000), Swanton (2003), American Heart Association(2004) consistent diabetes and obesity were independent predictors of sternal surgical site infection following coronary artery bypass grafting.

Also in the present study, it was found that half of subjects in study and control group were complaining from chronic obstructive pulmonary disease. However, Paletta *et al.* (2000), Keogh(2003), American Heart Association(2004),

Adam (2005), Drain and Forren (2009) and Morton and Fontaine (2009), emphasized that patients complaining from chronic obstructive pulmonary disease lead to impaired sternal wound healing.

In this context finding that all patients who participate in study and control group were using antibiotics, this is in agreement with those of Paletta *et al.*(2000);Trick *et al.* (2000) and Abd El Aziz *et al.* (2007) who mentioned that, the use of antimicrobial prophylaxis surgical procedures is one of the measures used to prevent the development of a surgical site infections.

The present study mentioned that more than two thirds of the patients in study and more than one third in control group were using anticoagulant. This agrees with those of, Kern (2003), and Punder (2005) who recommended that patients with mechanical prosthetic valves will require warfarin anticoagulation for life to prevent thrombosis and embolism.

Based on present finding mentioned that more than half of the patients in study and two thirds in control group have normal laboratory values of prothrombin time in preoperative period, while more than two thirds in study and more than half in control group have abnormal values as regard prothrombin time in postoperative period, this may be related to anticoagulation therapy.

The present study revealed that, more than two thirds in study and control group have normal laboratory values as regard serum sodium, serum potassium, calcium, and magnesium. This is in with accordance Noronha and Matuschak(2002), Dlercks (2004), Palmer(2006) and Urden *et al.* (2006), who mentioned that normal serum potassium levels are 3.5 to 4.5 mEq/L. Hyperkalemia and Hypokalemia elicits significant changes in the electrocardiogram (ECG) and impairs myocardial conduction.

Regarding glucose level two thirds of the patients in study and more than two thirds in control group have normal values as regard glucose level in preoperative period. In addition Garber *et al.* (2004) and Wynne *et al.* (2007) consistent the detection of increased blood glucose (more than 110 mg/dl) during a fasting state may indicate diabetes mellitus.

The present study showed that, the highest percentage (33.33 % and 26.67 %) in study and control groups respectively were having knowledge about rest and sleep. It also showed that most of patients had a general lack of knowledge in both groups about other items. Level of knowledge was insufficient this may be due to inavailability of training programs and lacking of continuous educations. This result was in agreement with Bedier (2005) who found that their was lack of patient's knowledge about pre and post operative care which predict poor recovery outcome

After implementing of the educational program study group patients had a highly significant improvement than those of control ones in relation to all items of knowledge. In this respect, Jennifer (2003) and Charlson *et al.* (2006) found that, applying nursing intervention postoperatively plays a major role in patients' improvement of knowledge and recovery.

As regard level of preoperative nursing care practice for open heart surgery patient, more than half of the patients in both groups had knowledge about performing foot and leg exercise. It also revealed that more than one third in study and control groups has no knowledge about how to perform coughing and breathing exercises, arm and shoulder exercise. According to American College Sports Medicine (ACSM, 1993) guidelines and Urden *et al.* (2006) recommended that exercise is important in the maintenance of the healthy heart.

Based on present finding assessment of practice level about post operative nursing care among patients in study and control groups, approximately an equally more than two thirds of patients in both groups have knowledge about nursing care of urinary catheter, activities and exercises in intensive care unit. It also showed that lacking of patient's knowledge about patient observation in intensive care unit, nursing care of nasogastric tube, and nursing care of chest tube in both study and control groups.

Regarding post operative activities, Charlson and Islam (2003) stressed that, following the cardiac surgery; the patient must be encouraged slowly to resume an active life, while minimizing the risk associated with overexertion. On the other hand Gerald and Fletcher (2007) . Abdel Monem (2008) illustrated that, active but not restrictive range of motion of extremities is also well tolerated early after cardiac surgery as long as activities do not stress or impair healing of sternal incision while patient become stable and early ambulated from bed.

As regards discharge instructions for open heart surgery patients, more than one third for study and control groups has had knowledge about how to perform walking exercise. Backer *et al.* (2003) and Punder (2005) recommended that a daily walk is sufficient to gain health benefits for patients after open heart surgery.

Before program implementation (pre-test) there was unsatisfactory level of knowledge. The implementation of educational program showed an improvement in patient' level of knowledge regarding all information related to open heart surgery. This has improved immediately after the program implementation and remained in the follow up.

The present study revealed that, before program implementation the patient did not have any

background or information about level of practice in preoperative, postoperative nursing care and discharge instructions for open heart surgery. Post program implementation their were significant improvement in patient' level of nursing care practice about open heart surgery preoperative, postoperative and discharge instructions on immediate post-test and follow up test.

According to Morton *et al.* (2005); Morton and Fontaine (2009) effective preoperative teaching program for patient before open heart surgery is important to help the patient in rapid recovery and prevent postoperative complications. The surgical procedure, the intraoperative and postoperative experiences are explained.

In the present study there were statistical significant differences in improvements throughout the educational program phases among study group regarding total score of knowledge and practice about open heart surgery.

The study in the line with those of Morton *et al.* (2005); Morton and Fontaine (2009) ; Okkonen and Vanhanen (2006) who emphasized that after cardiac surgery the patient may experience pain resulting from the chest or leg incision. In addition Wynne *et al.* (2007) and Osborn (2010) illustrated that the goals of nursing management is a thorough assessment of the patient's pain using a pain scale, provide a calm environment, adequate period of rest and sleep, administration of analgesics based on the report of pain intensity.

In present study the scoring system used is of Southampton Wound Assessment Scale to assess surgical wound infection in patients, the wounds graded before discharge and after 2 weeks postoperatively. In the present study, more than half of the patients in study and control group were having normal healing with mild erythema predischarge, while in follow up phases all patients in study group and more than two third in control group were having normal healing with mild erythema. In addition Bailey *et al.* (1992), Morris (2003) and Punder (2005) devised the Southampton Wound Assessment Scale to assess surgical wound infection in patients following surgery; the wounds were graded before discharge and 10-14 days postoperatively into one of four categories; normal healing, minor complication, wound infection, and major haematoma.

Based on the study results; it was clear that there were a significance difference as regard the relation between hospital stay and ICU stay and incidence of infection. Eagle *et al.* (2004), Morton and fontaine (2009) supported that length of stay in ICU and hospital environment after cardiac surgery increased risk for sternal surgical site infection.

It was found that in the present study there was significance difference as regard to relation

between housing condition and incidence of fever, delayed wound healing and pneumonia. This in line with Minohara *et al.* (1993) and Campbell (2000) and DVLA (2003) who found that poor housing condition increases incidence of surgical site infection.

It is the fact that study documented the statement of role of the nurse play a vital role in the prevention of SSIs in patients with open heart surgery, identification of early signs of infection are vital to the prevention and optimum treatment of SSIs. The critical care nurse must be integrating theoretical knowledge, assessment skills, and problem solving ability to provide optimal nursing care and maintain high quality outcomes for open heart patients.

Conclusion:

Based on the result of the present study, it can be concluded that; Significant differences in improvements throughout educational program phases among study group regarding total score of knowledge and practice about open heart surgery. A significant relation was existed between age, nutritional status, diabetes, hospital stay, ICU stay and incidence of delayed wound healing among study group.

Based on results of the present study, the following can be recommended:

I. For patients:

1. Patients who have had valve replacement require additional verbal and written information about protecting their prosthetic valve from infective.
2. The patients must understand the importance of oral hygiene and visiting a dentist regularly because dental infections can affect the valve prosthetic.
3. Tell the patients about importance of regular follow up in regular time.
4. Advice the patient regarding effective education and information are required to enhance understanding of drug therapy (anticoagulant drug).

II. For nurses:

1. An in-service education center should be established within Assiut University Hospital to improve nursing staff level of knowledge and performance.
2. To reduce the rate of infection, implementation of universal precaution and comprehensive education are required.

III. In services:

1. Follow-up care for patients with open heart surgery phone calls, home health visits and clinic visits would help to pinpoint problems and solve it.

2. Establishment of specialized cardiac clinics in all health centers to help guiding and caring for patient with open heart surgery.

IV. For research (future study):

1. Importance of doing separate studies of open heart surgery helpfully lead to more effective and preventive – based strategies for future.
2. Studies should be done for those patients who high risk for infection

Abstract: The paper aims to examine gender differences in money attitude among college students. Using the stratified sampling method, 2,340 college students from six public and five private colleges were studied. The findings indicate gender differences for different dimensions of money attitude, in which males were attached to money as a power/prestige tool while experiencing anxiety and having a retentive attitude toward money. Meanwhile female students were conservatively minded about money, as well as being attached to money for self-gratification purposes. [Leila Falahati, A Comparative Study in Money Attitude among University Students: A Gendered View. *Journal of American Science* 2011;6(3):1144-1148]. (ISSN: 1545-1003).

Keywords: Money Attitude, Gender, University Students, Financial Behavior,

1. Introduction

Money attitude and behavior have been a common cause of concern among economists, psychologists, and sociologists for over three decades. The majority of studies have recognized different aspects of money, demographic variables that are associated with money attitudes, and frameworks based on psychometric theories to explain financial behavior (Masuo, et al., 2004). Studies of financial issues revealed that attitude to money play an important role in determining a person's financial management and level of financial well-being (Joo and Grable, 2004; Porter and Garman, 1993; Shim, et al., 2009). A number of research findings emphasized that, generally, persons with stronger perceptions and positive financial attitudes tend to be more satisfied with their financial appraisals (Joo and Grable, 2004) and have more effective money management. In respect of financial matters, previous research generally proposed that past experiences formed attitudes toward money.

Evidence suggests that attitudes precede the development of money behavior (Roberts and Jones, 2001), in other words, money attitude contributes to predict financial practices (Dowling et al., 2009; Shim, et al., 2009). Attitude has been defined as "a tendency to act in a favorable or unfavorable way toward an object" (Eagly and Chaiken, 1993). Concerning money, Lown and Ju (1992), proposed that our attitudes and feelings surrounding money are integrated into our lives and, thus, motivate behavior in subtle ways.

In this respect Lim and Teo (1997) studied a sample of undergraduate university students in Singapore, and found that students who experienced financial hardship were more likely to use money as a form of evaluation, be more generous to the less fortunate, and have higher levels of financial anxiety compared to students who had not experienced financial hardship (Lim and Teo, 1997). Abelson and Prentice (1987) indicated that the ways in which individuals define their relations to material possessions reflect their general beliefs and values about money, which are typically influenced by past experiences.

The studies of money attitude among university students indicate that males and females understand money differently. Previous researchers who have examined the relationship between socio-demographic variables and money attitudes concluded that males and females have different beliefs about money (Allen et al., 2008; Hayhoe et al., 2000), which is due to the different financial socialization during childhood (Hira and Mugenda, 2000; Lim et al., 2003). The results of financial attitude studies (Dowling, et al., 2009; Hayhoe, et al., 2000; Lim, et al., 2003; Masuo et al., 2002) among college students revealed significant differences between male and female students in money attitude dominants.

Gender theories suggest that men's and women's perceptions are different, in part, due to socialization (Hira, 1997). However, it is well documented (Gutter et al., 2009; Newcomb and

Rabow, 1999; Shim et al., 2010) that families use different strategies to financially socialize boys and girls, which includes protecting girls from financial issues, and encouraging boys to participate in family financial decision making and practices (Newcomb and Rabow, 1999).

Lim and Teo (1997) conducted a study on a sample of undergraduate university students in Singapore, and found that students who experienced financial hardship were more likely to use money as a form of evaluation, be more generous to the less fortunate, and have higher levels of financial anxiety compared to students who had not experienced financial hardship (Lim and Teo, 1997). In addition, the findings of Lim and Teo (1997) showed some gender differences, with males often using money as a means of evaluation compared to females.

Later Lim et al., (2003) conducted a study among the Singaporean Chinese, which supported that men were more concerned about the power and anxiety dimensions, while women were more concerned about the budget, retention and evaluation dimensions of money attitudes. Lim et al., (2003) concluded that gender differences in money attitude might relate to the variation of socialization and traditional gender role expectations, especially in the Asian context. Men expect to be the breadwinners and the head of the family; therefore, men have a power/prestige money attitude. However, since women are expected to hold family roles they are attached to budget and retention money dominants.

Furthermore, Lim et al., (2003), following a review of the literature (e.g. Prince, 1993), indicated that women are more likely to view money as a means for attaining gratification, by allowing them, among other things, to acquire treasured possessions. He mentioned that, relative to men, as women are prone to underestimate their knowledge in financial matters (Goldsmith and Goldsmith, 1997), they may be more anxious about their finances and other finance-related matters (Lim, et al., 2003).

The findings of Hayhoe et al. (2000) among college students suggest that males tend to be more obsessed with money than female students, while female perceptions were influenced by money attitude of power/spending and retention. Finally, the results of Baker and Hagedorn (2008) among students revealed that males tend to score higher on both power-prestige, and on frugality-distrust. Furthermore research findings indicated that students perceive a higher level of financial problems due to a negative attachment to money and lack of financial management skills (Hayhoe et al., 2005; Hira and Mugenda, 2000; Kidwell and Turrissi, 2004; Norvilitis et al., 2006).

However, gender differences in financial attitude may result in differences in the level of financial knowledge, which, in turn, has a significant effect on financial behavior and financial well-being accordingly. In addition, money attitude is the focus of financial planners, since understanding how money attitudes relate to investment and savings behavior provides an overview for planners to provide more practical programs to enhance students' financial management skills accordingly.

2. Materials and Methods

2.1 Instrumentation

Financial attitude was measured by adopting six dimensions of Furnham's Money Beliefs and Behaviours Scale (MBBS) and adapted to the Malaysian context. Furnham's (1984) scale comprised six dimensions obsession, power/ prestige, retention, security, inadequacy/ anxiety, and effort /ability. However, based on the Malaysian context the self-gratification dimension was replaced with the effort/ability dimensions and all the statements were developed for the Malaysian context as well. The total score money attitude and six dimensions were computed by summing the scores of 1 to 4.

2.2 Sample procedure and sample profile

Data were collected using a stratified sampling method at six public and five private universities across Malaysia. A self-administered questionnaire was used as the data collection methodology. Of the 2,500 students who responded to the survey, 40.4% were male and 59.6% were female students; 71.4% were Malay being the major ethnic group in Malaysia, 21.7 % were Chinese, 5 % were Indian and others (.8%). The mean age of the respondents was 21 years. Students from public universities were 60% while others, 40%, studied in private universities.

2.3 Data Analysis

To determine gender differences in money attitude the mean comparison t-test was conducted between male and female students.

3. Results and Discussions

The results of the t-tests were given in Table 1 indicated that there were no statistically significant differences in the money attitude score; however significant differences were observed all money attitude components between male and female students except in obsession attitude. Given results revealed that male students (M= 8.5) are used money as power/prestige power/prestige means, compare to female students (M= 7.62). Findings of t-test indicated on the statistically significant difference

$t=8.811$, $P\leq.00$, between male and female students. In addition male students have higher level of anxiety ($M= 7.35$) about money while female have a lower level of anxiety ($M=7$), and male students are more retentive ($M= 4.16$) than female students ($M= 3.93$). Findings of t-test given in Table 1, indicated on statistically significant differences in anxiety ($t= 4.4$, $P\leq.00$) and retention ($t=3.97$, $P\leq.00$) between male and female students.

Results of mean comparisons revealed that female students ($M= 7.82$) use money for self-gratification and celebrate to compare to male students ($M= 7.27$), in addition female students ($M= 9.86$) are more conservative in money issues than male students ($M= 9.52$). Results of t-test indicated on the statistically differences in self-gratification attitude ($t= -6.69$, $P\leq.00$) and conservative attitude ($t= -4.82$, $P\leq.00$), between male and female students. The findings revealed that male students are more concerned about money.

Table 1: The Result of the t-Test for Financial Attitude

Items	Male	Female	t	Sig
Financial attitude	48.26	47.82	1.42	.136
Obsession	11.45	11.58	-1.207	.227
Power/Prestige	8.5	7.62	8.811	.000
Self- gratification	7.27	7.82	-6.69	.000
Anxiety	7.35	7	4.4	.000
Conservative	9.52	9.86	-4.82	.000
Retention	4.16	3.93	3.97	.000

* df :2145

These results are consistent with past findings, which suggest that males are more concerned about money than females (Barber and Odean, 2001; Funfgeld and Wang, 2009; Norvilitis, et al., 2006). The findings revealed that female students are more obsessed (Hayhoe et al., 1999), and security minded about money (Masuo, et al., 2004; Wilhelm et al., 1993), however, in contrast with their conservative attitude towards money, female students use money for self-gratification. Male students are more concerned about using money for power/prestige (Lim, et al., 2003) and are retentive and have anxiety (Lim, et al., 2003) about money issues. These findings indicate that while men use money to gain prestige and spend money to have influence on others, they experienced more stress about money and were even reluctant to spend money on necessities, such as buying books.

4. Conclusion and Implications

The main aim of the present study was to determine gender differences in money attitude

dimensions among students. The findings reveal that in a comparison of money attitude components, male students show more likelihood of demonstrating power/prestige, higher anxiety and retention attitude toward money than females. In contrast, females have a self-gratification and more conservative attitude toward money. There are no differences in the money attitude score and obsession attitude, between male and female students. The attachment of male students to money as power/prestige indicates that male students use money as a tool to influence others, which may increase the likelihood of experiencing a higher level of debt to achieve more power in financial matters. In addition, male students are retentive and more anxious about money, which indicates that they are also worried about their financial situation. Together these factors indicate that male students are attached to negative aspects of money and although they use money as a source of influence on others, they experience anxiety and have a retentive attitude toward money. Female students use money for self-celebration and spend money in order to reduce stress. Females have a conservative attitude toward money and are secure minded about money issues. It can be concluded that female students have a more positive attitude toward money than male students.

The findings of the present study indicate that both male and female students perceive money differently, which may be due to differences in the socialization process and past experiences about money or may even be related to the differences in financial skills and knowledge between male and female students. However, it is acceptable among researchers that differences in money attitude may result in different financial management, which should receive more attention by scholars and financial practitioners. Therefore, to enhance students' attitude toward money, policymakers should understand that providing educational programs to enhance the students' attitude toward money is more important than providing financial support and educational loans.

Policymakers should consider enhancing students' attitude toward financial aids among college students. Based on the findings of the present study it is recommended that further research be conducted to understand attitude formation and the factors that predict money attitude among male and female students. In addition, since the main part of attitude is formed during socialization, financial education programs may be provided for families as well. Students may not be the only target group in educational programs, as all attitudes, skills, and habits are formed during early childhood by families and reinforced by other socialization agents in later

life. Therefore, the improvement of family financial knowledge, attitude and skills is important to students. These findings should motivate all financial

professionals to encourage schools to include personal finance in the school curriculum.

Abstract: "Time" is one of the existential aspects of human and, Man always finds himself bounded by the time, as if man is its captive and has no way out of such captivity. Mulla Sadra and Bergson are two philosophers from two different philosophical schools, who have opened new horizons and masterminded new patterns in their interpretation of time. Mulla Sadra and Bergson believed that the reality of time should be interpreted in relation to existence. Mulla Sadra conceives time as a reality which is abstracted from the existence quality of material being; Bergson also conceives time as being synonymous with motion and calls it a duration (duree), which can be comprehended only through consciousness and pure intuition, and forms the foundation of our existence. In this paper, after elucidating time from viewpoints of these two philosophers, we will try to create proximity between these two points of view and open up a window for conjunction and adaptation.

Keywords: Bergson; Mulla Sadra; time; duration

1. Introduction

Time is one of the fundamental subject matters that have always engaged Man's thought and mind. The background of the problem of time goes much farther than that of metaphysical thought; and in no historical period of human life it has been pulled out of the hideout of his mind and thought. For him, every moment of time is important and he has bitter and sweet memories of those moments. In every moment, human has paid careful attention to the depth of the reality of time and has sought to discover its untold secret. Time is a subject matter, which in addition to philosophy, has reserved an outstanding place in contemporary art and science. It is a problem which no scientist has been - never and in no period and under no philosophical system - needless of thinking about it. To this end, the problem of time is considered to be a conjunction for many scientists and philosophical schools; and although it has a general meaning, which is apparently comprehensible to the public, its reality is amongst the most unfamiliar and the most unknown aspects of life.

2. Time, from a Historical Approach

The history of thought shows that cognition of "time" and its definition has a long-standing background as such that centuries before the beginnings of philosophical discussions in Greece, followers of Zurvanite religion in ancient Iran believed in two forms of time: 1. The passing time (to which we are captive) 2. The existential time (which is one of hypostases of the Divine Essence, while the other two are: Ahura Mazda and the Devil). According to Zurvanite religion, in the absence of time nothing

could be possible. Basically, by limitation of the "time" in this religion, existence emerges (Ebrahimi Dynani). It should be noted that followers of Zurvanite religion believed in the archetype of time, which was known as "Zurvan"; they considered Zurvan as the first being, an everlasting & eternal subject, and creator of the world.

In Plato's viewpoint, time has come to the existences in association with the creation of the world, and serves as a link between the world of being (eternal) and the world of becoming (temporal). Plato aimed to create a link or connection between the sensible world and the intelligible world and time is playing such a role and will be terminated by the end of the world:

"... The master thought of creating a moving picture of eternity. Striving for this goal and meanwhile trying to create the required order and system in the world, he made a constant picture of eternity - which is incessantly in unity and immobility. This picture is constantly moving on the basis of numerical plurality and is the same thing that we call "time" ... anyway, time and world were created together, so that if one day they are expected to be annihilated, they would be annihilated together ... (Plato).

Aristotle, with his natural and mechanical vision to creation, considered the time as the result of continues and circular motion of the first heaven; a motion which, in his view, penetrates from outside and proves the existence of the Creator. He says:

"We would realize existence of the time only when we recognize motion by diagnosing before and after of the motion; and it is only after recognizing before and after of the motion that we say time has passed" (Aristotle).

Therefore, in Aristotle's point of view, motion justifies existence of time and if we do not perceive the motion, we could not perceive time. Plotinus also believed in stability of the One and nous, but considered the universal soul to be a variable, whose changes are the origin of creating creatures and events in the world. In this perspective time emerges in soul and nature, as if he considered time as continuation and perpetuation of the life of soul (Nasrollah). The Islamic philosophy in its early stages of evolution and prosperity was under the influence of Greek thoughts, especially those of Aristotle's. Accordingly, most definitions are inclined toward the thought of Aristotle, and this is clearly seen in ideas of Alfarabius, Avicenna and, Averroes who usually consider time as an effect of motion and relate it to the first heaven. A few number of Muslim theosophists considered time as an fantasy concept, but some other medieval theosophists and philosophers believed in both spiritual and material time (Najafi). Kant in his philosophy took into consideration the same role for "time" that has been given to "existence" in Islamic philosophy, especially in its Sadrian style (Hadad Adel). Kant considers time as a priori condition for each experience and internal and external sensitive intuition. Heidegger too would consider time as the only possible horizon for emergence of existence and believes that time and existence, are interdependent on each other and thus cannot be separated. In his view, time is neither physical nor cosmic, but has an original and fundamental proportion with "existence" (Heidegger).

As it was mentioned earlier, most Muslim philosophers - especially the Peripatetic philosophers - followed Aristotle in the matter of "time". Avicenna in his "al-Isharat al-Tanbihat (Remarks and Admonitions)," writes about the essence of time as follows:

"And know that renewal (getting new), is not possible without changing the mood; and changing the mood is not possible without a subject possessing the power of changing the mood. This connection is dependent on motion and a moving; that is to say to variation and variable, especially anything, in which connection and non-interruption is possible; that is to say the circular positional motion. This connection is measurable, because "before" is sometimes closer and sometimes farther. Therefore, it is the same quantity that measures variation and transformation. Such a thing [with the said features] is the "time". Time, is the quantity of motion, not in terms of distance, but in terms of transpositions which do not come together" (Avicenna). Accordingly, in view of Avicenna "time" is an essential concept, which is placed in the Aristotelian table of categories and

because of its motion, overcomes the objects. Mulla Sadra usually uses the same statement; but after encountering vague and controversial questions, he suggests a novel theory about the time, and although he does not abandon the Aristotelian physical time, he does not consider it as being authentic. He considers physical time as an offshoot of the existing time.

3. Existence of time

Mullah Sadra in his "Al-Asfar" brings about two reasons to prove the existence of time. He calls one of the two reasons "the physicist argument", in which he tends to prove existence of time through physics, which is the way physicists prove it by using physical preliminaries as discussed below:

1. Suppose that two moving objects start to move together and stop moving together, but the distance they take is not the same. For example, one takes 10 km and the other 15 km.

2. In the second assumption, suppose that both of the moving objects take the same distance but they neither move together nor stop together, or they start moving together but do not stop together, or they do not start moving together but stop together.

Now, in this assumption, we are witnessing two types of quantities. One is the static continuous quantity, which we call distance; and the other is the non-static continuous quantity that is time, which is abstracted from quickness and slowness of motions (Mulla Sadra).

Another reason that Mulla Sadra adduces is called "the theological method", and his purpose of choosing this title is to argue the priory philosophy, which is asserts as follows:

Every contingent thing is precedent to something prior to it, and this priority cannot come together with the subsequence. There is a type of precedence that could neither coincide with us nor come after us. Such precedence is the origin of abstraction of time which is inherently not capable of being converted to subsequent (Mulla Sadra).

4. Whatness of the Time

After discussing existence or nonexistence of the time in Mulla Sadra's thoughts, now we try to find out what the time is and what definition Mulla Sadra has offered in this regard. As it was mentioned earlier, Aristotle and consequently most Muslim philosophers believed that time is the quantity of motion; and motion means an accidental affair; that is to say motion takes place in accidents and not in substance. Therefore time is the same static continuous quantity. However, we will see here that while Mulla Sadra accepts that time is the quantity of motion, his interpretation of time and motion differs

from those of Aristotle and most Muslim philosophers; because, on one hand Aristotle considers motion to be related to the accidents of substance, while Mulla Sadra believes that motion is within the substance itself and not away from it. Furthermore, Aristotle considers time as the quantity of rotating motion of the heaven but Mulla Sadra considers it the quantity of the motion of the substance which stays as the fourth dimension besides the three dimensions of the physical substance. His phrase is as follows:

"So time is a quantity of nature whose essence is renewed in terms of essential precedence and subsequence as such that the mathematical body is the degree of being natural in terms of the acceptance of the three dimensions. Therefore, there are two extensions for the nature (physical substance) and there are two quantities for it; one gradual temporal that accepts division into temporal precedence and subsequent, and the other special repulsive which accepts division into special precedence and subsequent. The ratio of quantity to extension is the ratio of the specified to the vague which are one in terms of existence but are different in terms of consideration" (Mulla Sadra).

He then explains his views, reminding that time is not a biased and independent issue, like darkness and brightness, and its existence is rather inseparable from the existence of motion and consequently from the existence of substance. It is only in our subjective analysis that we separate time from of motion and ultimately from the substance. His statement is as below:

"One, who ponders a bit on whatness of the time, would realize that it has merely an intellectual consideration, and happening of it to a subject in terms of existence, is not like external accidents of the things, like blackness, hotness, etc. Time is rather of analytical accidents of its subject and existence of such accident in outside cannot be separated from existence of their subjects; because, the relationship between them is merely subjective..." (Mulla Sadra). It is however understood from Mulla Sadra's statement that time (and motion) is amongst philosophical secondary intelligible whose origin of abstraction is in the external world, but has no instance there. The external world is as such that mind will abstract time from it with the help of analysis.

But in the world outside of our mind there is no being as time against the physical substance as in the case of motion, what exists in the outside world is the same physical substance that notion of the concept of motion is abstracted from observing its presence in point "A" and comparing it with its existence in point "B".

Therefore, it seems that in the opinion of Mulla Sadra time is neither an objective or biased entity nor a completely subjective entity, like the logical secondary intelligible or illusions that are the outcomes of man's misconception; it is rather a subjective being, derived from the background and origin of objective abstraction.

In fact, in the opinion of Mulla Sadra, time, motion and physical being are of a same existence. He rejects the duality between motion and time, as he does not believe that motion and time are external accidents for the material being. Mulla Sadra has a very precise statement in this regard, which is rooted in his ideas about substance and accident. Mulla Sadra's opinion on the relation between substance and accident is totally different from those of Aristotle and Avicenna. He views accidents and attributes of each object in terms of existence, as the degrees and positions of the existence of substance. According to him, each attribute and accident in an object is exactly attribute and accident of the specific existence of that object. Thus motion of an object is the identity of that object. Accordingly, Mulla Sadra extends the motion to the category of substance and figures it as the amount of motion in substance. From his point of view, time is the essential appraiser of material substance and, therefore, all substances and material phenomena have their own specific time because time is one of the many aspects of their existence (Akbarian). Thus, Mulla Sadra considers time as a visible extension or the fourth dimension of material existence and in his point of view temporality of the objects is an indication of some sort of extension in their existence. In his detailed analysis, objects have two extensions; one in the ground of space and the other in the ground of time. The special traction has three geometrical dimensions and the time traction is resulted from the inner flux of material universe:

"... The nature has two extensions and two quantities; one is gradual and temporal and could be illusively divided into 'before' and 'after' of the time; while the other is expelling and spatial and could be divided into spatial 'before' and 'after'" (Mullah Sadra).

The mentioned phrase is amongst the most important and enlightening expressions of Mulla Sadra about the time. The fact that time is the fourth dimension of material and has no other external existence except for this is a great discovery in discussion over "existence of the time".

Of course, the philosophical term the "fourth dimension" in the Sadrian philosophy should not be mistaken for the physical term "general relativity" of Einstein. The universe having for dimensions in Sadrian interpretation is a metaphysical concept which could be experimented. This dimension is not

a quantitative dimension but an "existential dimension", derived from the state of "being" of the material being and interferes in its "identity". In fact, "time" is a fluid and renewable identity from which the mind is capable of abstracting an intellectual consideration called "time". According to this statement, motion, and consequently time, do not undergo any categories and may not be regarded as an essential concept. It is rather a fluid existence which acts like the motion and fluid existence in the external world; and it is only in the subjective analysis that mind can differentiate them. In order to understand the reality of time which is constantly renewed and is in fluidity and anxiety, one should to it and perceive it intuitive.

"They (substances) are existential identities which are by essence not under substance and quality and quantity other than these categories and species and geniuses; because, they are existences that have been imparted from affairs of the first right, they (pure beings) are effects of intellectual light and illuminating shadows of Him – the Almighty" (Mullah Sadra).

5. Time in Bergson's thought

The theories that have been presented about time before Bergson have usually emphasized on its quantitative aspects. Its qualitative characteristics have neither been a matter of question nor been paid the least attention. Bergson's point of view in the history of Western thoughts in this regard is being considered as a turning point. Bergson opposes the widespread interpretations of time and presents a new pattern. He considers the concept of time, as reflected in the current tradition of philosophy and physical sciences, as a spatial time and believes that these pretend to be measuring the time, while it is indeed the space that measures it. In this attitude, time has transpositions and belongs to the world of objects which is needed for giving order and regulating our motions and activities as such that is appropriates the social environment, but it is not the real time (Wall). Rather, the real time is a much deeper understanding which is in ourselves and belongs to ourselves which Bergson interprets as duration. In his point of view the real time is duration. Duration is absolute fluidity and dynamism. In Bergson's thought duration is being considered as multiplicity of conscious states which has unified his thought from his first philosophical work, "Time and Free Will", where it distinguishes between absolute multiplicity and multiplicity of conscious states, to the creative evolution.

In Bergson opinion, the unreal time is generated from our interpretation of space and in our normal everyday life we measure this time with such

matters as hours and calendar. Separation of time and space from each other and identification of two different times, one the unreal time which is resulted by the adjustment with space and dimension and, in other words, is a quantity and the other which is real time and means that the same duration which is a quality, is among outstanding points in Bergson's philosophy.

"There are two possible conceptions of time; one free from all alloys, the other temporally bringing in the idea of space" (Bergson).

"The concept of conventional time which is used in science, including mathematics, is together with the notion of space and in Bergson's opinion; this common and spatial concept of time is in fact abstracted from the real time, meaning duration. If we refer to our life and true experience of the time, we will find out time as duration; but when we build concepts or try to make an assessment of it we replace it with space and consider time to be spatial. In fact, this concept of time is a spatial or mathematical concept of duration.

For the sound interpretation of duration an example of Bergson himself would be effective:

1 –We imagine the material point "A" moving on a straight line with infinite length.

2. We imagine that "A" is a self-conscious being with intuitive knowledge of a succession which feels its own changes.

3. From this point two modes could be assumed:

a)"A" has an idea of the space.

b)"A" knows nothing about space, which we should accept this assumption in the understanding of duration.

4. We choose the first assumption that "A" is conscious of the space. Based on this assumption, "A" understands its successive approach as a line, because in this case "A" places itself somewhere above the line and thinks in a three-dimension space, because as long as we do not expect ourselves out of the line and become conscious of the free space around it, we could not imagine the line at all. The mistake that is being made by those who consider duration like space, but with a more simple nature, originates from this point. They would put psychic states side by side and make a line or chain out of it and imagine that space is not involved in this operation, while idea of a line in the absence of the involvement of space and perception of the free space around it has no meaning.

5) We choose the second assumption in which "A" has no idea about space. In this assumption "A" will not understand succession of its states and transformations in the form of a line. Instead, sensations will be added together like forces

and become harmonious like consecutive notes of a melody. Therefore, it is clear that a pure duration means a succession of qualitative changes which have influenced each other to the extent that have been melted in each other, there is no boundaries among them, do not tend to separate, and have no proportionality with numbers and counting that could guarantee imagination of space (Bergson).

Bergson considers negligence of the predecessors to the time as their lack of attention to continuity of time and presence of past in present and believes that the predecessors were only concerned about passage and wastage of time. Time for the predecessors was not theoretically significant because "duration" showed nothing but the destruction of their nature; while science deals with the fixed nature (Bergson).

In brief, several characteristics could be outlined for "real time" in Bergson's philosophy:

1 - Real time is a continuous reality whose components are so intermingled with each other that could not be distinguished from one another. There is an unbreakable unity between the past and the present. To further elucidate the problem, Bergson distinguishes two types of multiplicities in "Time and Free Will". The first is absolute multiplicity or distinctive multiplicity, which belongs to material objects that are located in place, and the other is a continuous multiplicity, which belongs to our conscious states and its elements are combined with each other (Bergson).

In Bergson's point of view multiplicity of conscious states is a qualitative multiplicity and absolute multiplicity is quantitative. These two temporal multiplicities would become further clear when we deal with our immediate experience, where Bergson elucidates it by providing an example. He says, for example, take our conscious of the successive strokes of the bell we are hearing, I may count the single strokes "in which case I shall have to separate them, and this separation must take place within some homogeneous medium in which the sounds, stripped of their qualities, and in a manner emptied, leave traces of their presence which are absolutely alike" (Bergson). This homogeneous medium can't be the time, because they can't persist in order to be added to others. Therefore it is space and a multiplicity which accompanies space and takes place in space. Bergson calls it an absolute multiplicity, and the spatial time on this basis is an absolute multiplicity. On the other hand, I may "I retain each of these successive perceptions in order to combine it with the others and form a group which reminds me of an air or rhythm which I know: in that case, I don't count the sounds, I limit myself to gathering so to speak, the qualitative impression

produced by which series" (Bergson). In this case, our attention is not towards any sound as a specific external single unit against the total sound; on the contrary we hear a melody or a tune in which single music notes melt or become fluid but join together and form an organic whole. Although sounds come individually and one after another, "we perceive them within each other ... its totality may be compared to a living being whose parts, although distinct, permeate an another because they are so closely connected" (Bergson). Therefore, in addition to the ability of projection of a medium or homogenous mediator which creates some kind of succession of distinct, coherent and unified units, we can this conceive of succession without distinction and think of it as a mutual penetration, an interconnection and organization of elements, each one of which represents the whole, and can't be distinguished or isolated from it except by abstract thought" (Bergson).

According to Bergson, thought this "succession without distinction" which is an indication of continuous multiplicity is basic characteristic of our consciousness and conscience because it is in the state of duration or real continuity. And duration is not a series of separate moments, rather every moment of it flows with other moments and instead of being a distinct and detached piece is a continuous process and constantly every new moment of it would be dipped with whatever it had been before (Bergson).

2. Duration is a pure quality which is only received through immediate intuition. As it was said earlier, duration is multiplicity of the conscious states. "What is duration within us?" a qualitative multiplicity, with likeness to number; an organic evolution which is yet not an increasing quantity; a pure heterogeneity within there are no distinct qualities" (Schwartz).

Heterogeneity is a feature of duration and when we talk about mathematical time we think of a heterogeneous mediator in which self-consciousness states have been put together like a space in order to form a multiplicity.

3. Duration is subsistence and in the light of the attention to the conscious states and life itself, it could be comprehended. The duration which is comprehensible through self-consciousness, because of being immediate of these perceptions is considered of the most irrefutable personal experience. The example that Bergson brings for this problem is that if I want to make a glass of water with sugar for myself, the more I try the less success I will gain, I have to wait until sugar dissolves. This minor point is highly informative. Because the time I have to wait for is no more that mathematical time which is being

imposed throughout the world history ... This conforms with my impatience; that is with part of my duration, which could not be prolonged or shortened deliberately. This is not thinkable, but is subsistence (Bergson).

4. Real time is unified with life and is not out of it, therefore wherever there is a sign of life, time is extensive. Time is real for life as it is for the empty upper part of the sand-glass, and its filled bottom (Bergson). Bergson's most beautiful expression about unity of time with the life is this immortal phrase: "wherever there is something living, a book is opened wherein time is being registered" (Bergson).

Wherever change is evolved, it will have duration as well. But, if motion is denied, duration would no more have a meaning. When each being is the result of its past, it would lose nothing in the passage of time; rather the more time moves on, the more will be added to its perfection and corpulence. Presence of the past in present is tantamount to the presence of all achievements of life in the status of man itself. Duration is not merely a moment replacing another moment; duration is constant progress of the past which gradually moves towards future and gets corpulent with its progress (Bergson).

6. Comparison between Mulla Sadra - Bergson thinking regarding time

1. There is an important distinction and separation in the opinions of the two philosophers. In Bergson's thought, the distinction between the unreal time and the real time is discussed as duration. Duration is undividable but the unreal time is spatial and therefore is dividable. In Mulla Sadra, as was mentioned earlier, unlike the predecessors the quantitative view to time is a curtailed, partial and incomplete interpretation of the time. In the opinion of Mulla Sadra time is within the existence trait of a temporal object which is adopted from the manner of its existence. Time accounts for the fluid reality of material beings. However, it should not be forgotten that the real time (quality time) from Bergson's point of view has been noted with respect to its manner of existence and, in this respect, greatly resembles Mulla Sadra's expression about time.

In the thought of the two philosophers, the unreal time, is quantitative and therefore is measurable and real time as well, has no transposition, before and after, beginning and end, and is not basically capable of having transpositions, while transposition constitutes essence of the unreal time.

2. As it has been mentioned, both the philosophers admit the possibility of access to the reality of time through presence and intuitive perception, which Bergson calls intuitive perception (Mulla Sadra holds

the same idea with regard to perception of the reality; yet he interprets the concept of "existence" a philosophical secondary intelligible like the concept of time). They also emphasize over this point that understanding and perceiving time, through conceptual encounter and reason, is not accessible and acquirable; in Bergson's words, what is obtained through reason in proximity with time is a fabricated time, false and unreal, and mathematical and quantitative not real and true (though Mulla Sadra does not consider conceptual analysis of time fabricated and false like Bergson).

3. In Sadrian philosophy, substantial motion and time acquire a closely intertwined relation to such an extent that in the understanding of each one of them the other cannot be neglected. He brings a reason to prove the substantial motion that one of its preliminaries is based on understanding and perceiving the reality of time. Mulla Sadra, through understanding the reality of time as one of the fluid and transient aspects of the dimensions of material beings, offers a reason on the existence of motion in the substance. On this basis, he considers every material being to be temporal and having time dimension; and because every being which has such a continuation within its essence would be gradually obtainable and would enjoy wide range of components in the span of time, he comes to the conclusion that existence of each physical substance is gradual, transient and renewable and when interfering in a temporal phenomenon, this is the same time of substantial motion; termination of the motion of substance is tantamount to termination of time and no physical substance could be assumed being apart from time. Generally speaking, in this view, the world is a fundamental motion; and this motion and evolution is the same as its existence and identity. In fact, the entire universe is a moving object with a single movement; every existing and every incident is a part of this single motion which is renewed and finds new creature in every single moment. In this case, the exact concept of substantial motion is that all particles of the world are constantly wasted and renewed. This constant wastage and renewal embodies not only all status and accidents of the objects, but also their entire identity and existence. Mulla Sadra also attributed this to human existence. In his opinion, the reality of human existence is a gradual and fluid reality whose motion begins from the first stages and finally, reaches the status of abstraction and understanding of the Holy reality. Time, like existence, has a close relation with the constant and continued creation. Every material phenomenon is transformable in its essence and substance and its existence at any given moment, is different from its existence in another moment;

therefore, the act of "permanent creation" by the divine absolute essence is underway - uninterrupted. Bergson, like Mulla Sadra, views termination of motion in the world as termination of time and, as was mentioned before, stresses that: Human and the world, which are constantly renewing and rehabilitating their existence, are considered as duration. "The world is duration. The more we ponder about the nature of time, the more we will understand that continuation, meaning innovation and creation of forms and constant preparation of issues, is absolutely new" (Bergson). If not exaggerated, some of the expressions of Bergson are so similar with remarks of Mulla Sadra and it seems that they have been quoted from Mulla Sadra's Al-Asfar. From Mulla Sadra point of view, in the turning points of physical and chemical transformations, a substantial evolution occurs and a new "self" is created in the world, but such renewal is a constant and permanent issue which infiltrates every particle of the creatures in the world. Therefore, creatures of this world at any moment achieve a new identity.

4. Among differences between the two philosophers which could be noticed about the time is that Mulla Sadra in addition to the favor shown to the existential dimension of the reality of time, also considers its conceptual, reasonable and quantitative dimensions as well and defines each of them in its special place. But, Bergson terms time, or in his own interpretation, the spatial time as fabricated and false time and not only regards no place for it, but denies it as well.

Of course, since the two philosophers come from two different philosophical schools, perhaps through greater pondering and deliberations, their differences even in the topic of discussion, could be further identified, but in this paper we were after taking steps in the path of comparison leading to conjunction and highlight common views the two philosophers share with each other. Therefore, we relinquish from focusing in detail on the differences of the two philosophers.

7. Conclusion

Given that Mulla Sadra and Bergson, due to their philosophical origins, have no intellectual affinity and background for mental relationship, however, their approach towards time is an indication of a new and fresh look which has not been given any attention by the predecessors. Of course, this does not mean that opinions of the two philosophers are fully compatible with regard to the time. Similarities that exist in the proximity of the two philosophers in this subject and comprehension and perception of time through the passage of presence and intuition, which

is in fact the basis and fundamentals for Bergson's philosophy as well as qualitative look and encounter with it in presence and in existence suggests unanimous look of the two philosophers to this reality, give us and excuse for comparing them. Of course we did not speak of their differences, because with regard to their adherence to two distinctive philosophical schools; addressing the differences would make speech tedious and thus would not realize our purpose and ultimate goal from this written article.

Abstract: Hashimoto's thyroiditis is a localized autoimmune disease which is characterized by an overactive immune response of the body directed against its own tissues causing prolonged inflammation. Numerous cytokines have been identified at sites of chronic inflammation such as arthritis, thyroiditis and periodontitis as interleukin 6 and interleukin 15. Adiponectin, adipocyte-derived proteins, have immunoregulatory properties and it controls immune responses and inflammation. This study aimed to determine the levels of adiponectin, interleukin 6 and interleukin 15 in patients sera of Hashimoto's thyroiditis with different thyroid functional states (hypothyroidism, euthyroidism and subclinical hypothyroidism). Subjects and methods: Seventy patients (8 males, 62 females) of newly diagnosed Hashimoto's thyroiditis (HT) in Al-Azhar University Hospitals were selected on the basis of high serum levels of anti-thyroid peroxidase antibody (TPO Ab). The patients were divided according to the thyroid function tests into three groups: Free triiodothyronine (FT3), free tetraiodothyronine (FT4) and thyroid stimulating hormone (TSH). The first group was patients with hypothyroidism (H) (3 males, 25 females with mean age 46.5±6.23) with increased TSH and decreased both FT3 and FT4; the second group was patients with euthyroidism (E) (2 males, 16 females with mean age 48.77±6.56) with normal TSH, FT3 & FT4 and the third group was patients with subclinical hypothyroidism (SH) (3 males, 21 females with mean age 48.95±6.61) with increased TSH and normal both FT3 and FT4. The fourth group is a healthy control group (C) (2 males, 15 females with mean age 49.52±7.55) with matched age, gender and body mass index (BMI) with the patient groups. TPO Ab, FT3, FT4, TSH, adiponectin, IL-6 and IL-15 serum levels were measured in all groups. Obtained results revealed a highly significant increase in the mean serum levels of TPO Ab, IL-6 and IL-15 were detected in each of the three patient groups compared to the control group. A positive correlation between adiponectin and each of BMI and WHR in group II (E) only was detected. Also, a highly positive correlation was found between IL-6 and IL-15 in the patient groups. On conclusion, IL-6 and IL-15 may have a possible role in the pathogenesis of Hashimoto's thyroiditis irrespective to thyroid function states. In contrast, the serum level of adiponectin may have no role in Hashimoto's thyroiditis.

Keywords: Hashimoto's thyroiditis (HT), interleukin 6 (IL-6), interleukin 15 (IL-15), adiponectin

1. Introduction:

Autoimmune diseases affect 5-10 % of the population and are characterized by an overactive immune response of the body directed against its own tissues causing prolonged inflammation. Endocrine autoimmune diseases include Hashimoto's thyroiditis (HT), Graves' disease and type I diabetes mellitus (Sieminska *et al.*, 2010).

Hashimoto's thyroiditis is the most common organ specific autoimmune disease. It is the commonest cause of primary hypothyroidism. An average of 1 to 1.5 in a 1000 people has that disease. It occurs far more often in women than in men (between 10:1 and 20:1) and is most prevalent between 45 and 65 years of age (Paknys *et al.*, 2009). The original study by Hashimoto indicated a striking increase in the number of lymphoid cells and

scattered plasma cells in the thyroid gland (Figueroa-Vega *et al.*, 2010).

Numerous cytokines have been identified at sites of chronic inflammation such as arthritis, thyroiditis and periodontitis. One of these, interleukin-6 (IL-6), is a major mediator of host response to tissue injury and infection (marker of inflammatory status) (Gani *et al.*, 2009). Also, there is evidence of overproduction of IL-6 in obesity (Olszanecka-Glinianowicz *et al.*, 2004) and autoimmune diseases such as rheumatoid arthritis (Hirano *et al.*, 1988), systemic lupus erythematosus (Chun *et al.*, 2007), allergic urticaria (Lawlor *et al.*, 1993) and Crohn's disease (Gross *et al.*, 1992). Among thyroid autoimmune diseases, increased IL-6 levels have been observed in Graves' disease (Salvi *et al.*, 1996), subacute thyroiditis, and aminodarone-

induced thyrotoxicosis (Bartalena *et al.*, 1994). IL-6 regulates growth and differentiation of thyroid cells and its expression in thyrocytes correlates positively with the degree of lymphocyte infiltration (Ruggeri *et al.*, 2006). IL-6 plays a major role in B cell differentiation and also enhances T cell proliferation and bone resorption. There is a significant correlation between tissue levels of IL-6 and the severity of the coincident inflammation. IL-6 is a 26-kDa glycopeptide whose gene is found on chromosome 7 (Dayer and Choy, 2010).

The cytokine interleukin 15 (IL-15, a protein of 114 amino acids) was first discovered due to IL-2 like stimulatory actions on T cells. The heterotrimeric IL-15 receptor comprises the α and β chains of the IL-2 receptor with a unique γ subunit. These shared receptor subunits most likely explain the similar T cell growth factor properties of both IL-2 and IL-15 (Van Heel, 2006). Several cell types can produce IL-15 including macrophages, keratinocytes, muscle cells, dendritic cells, endothelial cells and neural cells (Bigalke *et al.*, 2009). IL-15 has a number of activities including recruitment and activation of T cells, maintenance of T cell memory, stimulation of proliferation and immunoglobulin synthesis by B cells, natural killer (NK) cell proliferation, activation of neutrophils and inhibition of apoptosis (Quinn *et al.*, 2009).

There is evidence for crosstalk between adipose tissue and the immune system. Proper production of adipocytokines is needed to keep optimal immune responses. Overnutrition has been found to increase the risk of autoimmune diseases and, conversely, undernutrition has been associated with impairment of cell-mediated immunity (Otero *et al.*, 2006).

Leptin and adiponectin, adipocyte-derived proteins, have immunoregulatory properties and they control immune responses and inflammation. These adipocytokines play an important role in the pathogenesis of several autoimmune diseases such as rheumatoid arthritis, type 1 autoimmune hepatitis, lupus erythematosus, type 1 diabetes mellitus and autoimmune encephalomyelitis (Durazzo *et al.*, 2009). However, very little is known about adipocytokines production in autoimmune thyroid diseases (Lago, 2007). Sieminska *et al.*, 2008 have previously found elevated levels of adiponectin in Graves' disease, and hyperadiponectinemia was related to hyperthyroidism and to TSH-receptor antibodies.

The aim of the present study was to determine the levels of adiponectin, interleukin 6 and interleukin 15 in sera of patients with Hashimoto's thyroiditis with different thyroid functional states (hypothyroidism, euthyroidism and subclinical

hypothyroidism) to find its possible role in disease pathogenesis.

2. Subjects and Methods

Seventy patients (8 males, 62 females) of newly diagnosed Hashimoto's thyroiditis (HT) in Al-Azhar University Hospital were selected on the basis of high levels of anti-thyroid peroxidase antibody (TPO Ab) in the serum. Diagnosis of the patients was confirmed by typical hypoechogenic pattern on thyroid ultrasound, presence of a firm and symmetrical enlarged thyroid and thyroid biopsy if possible. Exclusion criteria: Patients receiving anti-thyroid drugs or L-thyroxine therapy were excluded. None of the patients had other autoimmune diseases as type 1 diabetes mellitus, rheumatoid arthritis, pernicious anemia or systemic lupus erythematosus.

The subjects involved in this study were divided into four groups. The first group was patients with hypothyroidism (H) (3 males, 25 females with mean age 46.5 ± 6.23) with increased TSH and decreased both FT3 and FT4. The second group was patients with euthyroidism (E) (2 males, 16 females with mean age 48.77 ± 6.56) with normal TSH, FT3 & FT4. The third group was patients with subclinical hypothyroidism (SH) (3 males, 21 females with mean age 48.95 ± 6.61) with increased TSH and normal both FT3 & FT4. The fourth group was apparently healthy subjects as a control group (C) (2 males, 15 females with mean age 49.52 ± 7.55) of matched age, gender and body mass index (BMI) with the patient groups; they had a normal range of TPO Abs, normal physical & ultrasonographic thyroid examination. BMI was calculated as the ratio of weight to the square of height, and waist hip ratio (WHR) was calculated by dividing the circumferences of the waist and hip. Blood samples were collected from the patients on diagnosis and centrifuged. The serum was kept frozen at -70°C until use.

FT3, FT4 and TSH were measured using an automated VIDAS machine (BioMerieux, France), by Enzyme Linked Fluorescent Assay (ELFA). Normal ranges were 2.5-8.3 pmol/L for FT3, 8.0-24.0 pmol/L for FT4 and 0.25-5.0 $\mu\text{IU/ml}$ for TSH.

TPO Ab was measured by commercially available enzyme immunoassay kits (Accu-Bind ELISA Microwells, Monobind Inc, USA) (Portman *et al.*, 1985). Values in excess of 40 IU/ml were considered positive for the presence of anti-TPO autoantibodies. Serum level of adiponectin was determined by quantitative sandwich enzyme immunoassay technique from Quantikine Research, USA (Kishore and Reid, 2000). Normal range for adiponectin was 0.86-21.42 $\mu\text{g/ml}$. Serum level of IL-6 was determined using AviBion Human IL-6 ELISA Kit, Origenium Laboratories, Finland and according to

the manufacturer's directions its normal range up to 3.12 pg/ml (Allen, 1997). IL-15 determination using Quantikine Research, USA according to the manufacturer's directions by ELISA technique and its normal range up to 3.9 pg/ml (Grabstein, 1994).

Statistical Analysis:

Data was statistically analyzed using SPSS program version 15 for windows (SPSS, Inc., Chicago, IL). The relation between each group from the three patient groups and the control group was done using ANOVA test. Post Hoc test f (LSD) was done to show the mean and SD of each variable. Determination of Pearson's correlation coefficient (r) was used for correlation between quantitative variables. P-value less than 0.05 were considered to have significant difference.

3. Results:

As shown in table (1); a highly significant (0.001) increase in the mean serum levels of TPO Ab, IL-6 and IL-15 in each of the three patient groups was observed compared to the control group. The serum adiponectin, BMI and WHR showed no

statistically significant difference among the groups. Regarding mean serum levels of FT3 and FT4, there was a significant (0.001) decrease in H group only compared to the control one. A significant (0.001) increase in the mean serum level of TSH was revealed in both H and SH groups compared to the control group.

As shown in table (2); the correlations between adiponectin & BMI and adiponectin & WHR, were significant (P<0.05) in group II only.

As shown in table (3); There was a significant positive correlation of serum level of IL-6 and IL-15 in the three groups (r= 0.941, 0.826 and 0.719 in group I, II and III respectively with p value <0.001 in the three groups).

Considering the serum level of IL-15 as in table (4), it showed no significant correlation relationship with TPO Ab in group I, II and III. A significant negative correlation was found between IL-15 and FT3 in group I (r=-0.389 & p<0.05) and group III (r=-0.505 & p<0.05). Regarding the correlation between IL-15 and FT4, a significant negative correlation was found (r=-0.538 & p<0.001) in group III only.

4. Discussion

Hashimoto's thyroiditis is a localized autoimmune disease which is characterized by the production of the antibodies against thyroid auto-antigens and infiltration of cytotoxic T cells in the thyroid gland leading to the destruction of follicles (Tagami *et al.*, 2010). It is originally described as stroma lymphomatosa which is featured as the formation of lymphoid follicles, marked changes in the thyroid epithelial cells, extensive formation of new connective tissue and diffuse infiltration of round cells (Hollowell *et al.*, 2002). The current study aimed to determine the levels of adiponectin, IL-6 and IL-15 in sera of patients with Hashimoto's thyroiditis with different thyroid functional states

(hypothyroidism, euthyroidism and subclinical hypothyroidism).

In the current study, a highly significant increase in the mean of serum level of TPO Ab was detected in the patients groups compared to control group as the selection of the patients in this study depended on the presence of high serum level of TPO Ab. Xie *et al.*, (2008) reported that TPO Ab is the hallmark of HT which could be detected in almost 95% of HT patients' sera. Paknys *et al.*, (2009) stated that Hashimoto's thyroiditis and Graves' disease are different expressions of a basically similar autoimmune process and the clinical appearance reflects the spectrum of the immune response in a particular patient. During that response, cytotoxic

autoantibodies, stimulatory autoantibodies, blocking autoantibodies or cell-mediated autoimmunity may be observed. Persons with classic Hashimoto's thyroiditis have serum antibodies reacting with thyroglobulin and thyroid peroxidase. These antibodies (particularly antibodies against thyroid peroxidase) are complement-fixing immunoglobulins and might be cytotoxic. In addition, many patients have cell-mediated immunity directed against thyroid antigens (Umar *et al.*, 2010). Also regarding TPO Ab, no significant correlations were found in this study between each of TPO Ab and IL-6 or TPO Ab and IL-15 in H, E or SH groups. This observation agreed with Prummel and Wiersinga, (2005) as they stated that considering the fact that high TPO Ab concentrations correlate with increased frequencies of Th-1 responsible for thyroid damage and the loss of thyroid function, it can be speculated that antibodies influence the level of TSH. However, Nielsen *et al.*, (2009) reported that the exact role of antibodies against thyroid peroxidase is unclear but it is likely that they promote the release of a variety of cytokines including IL-6, TNF- and IFN-.

A significant decrease in serum levels of FT3 and FT4 in group I (H) was detected as that group contained patients having HT with hypothyroid functional state. Also, a significant increase in serum level of TSH in groups I and III (H and SH groups). McCanlies *et al.*, (1998) defined HT with hypothyroidism by the presence of high titers of TPO Ab or thyroglobulin antibodies, elevated levels of TSH in the absence of medication, a positive medical history and/or a positive clinical examination. While, they defined euthyroid HT as elevated TPO Ab or thyroglobulin antibodies and normal TSH without the positive medical history or clinical examination seen with hypothyroidism. Xie *et al.*, (2008) revealed that patients with HT have a great deal of clinical status; in general, it is an inconvertible process of evolving from euthyroidism to hypothyroidism and the positive TPO Ab increases the probability of developing hypothyroidism but the progression rate of euthyroidism to subclinical and even to overt hypothyroidism is variable and the progression mechanism of HT is still unclear.

Regarding, adiponectin serum level, the current study showed that no statistically significant difference in comparing patient groups with control group. Durazzo *et al.*, (2009), Aprahamian *et al.*, (2009) and Ehling *et al.*, (2006) revealed that it is well known that adipocytokines as adiponectin have immunoregulatory functions and their concentrations are elevated in the peripheral circulation of patients with many autoimmune diseases such as type 1 autoimmune hepatitis, rheumatoid arthritis and systemic lupus erythematosus but the detailed

mechanisms of adiponectin actions remain unknown. Sieminska *et al.*, (2008) mentioned that very little is known about adipocytokines production in autoimmune thyroid diseases although they found elevated levels of adiponectin in Graves' disease and hyperadiponectinemia was related to hyperthyroidism and to TSH-R antibodies. However, the results of the present study agreed with Sieminska *et al.*, (2010) as they revealed that although overproduction of adiponectin is pathologically involved in collagen-induced inflammatory autoimmune diseases, their results showed no difference of serum adiponectin level was observed with regard to the presence of HT. No significant correlation was observed between adiponectin and TSH in the three groups. This is in contrary to Obregon, 2008 who found that TSH receptors have been found on several fat depots and in animal experiments, TSH directly influences adipose tissue and stimulates adipogenesis through these receptors on the surface of adipocytes. These findings suggest that the pathogenesis of autoimmune thyroiditis is different and independent of connections with adipose tissue as the explanation of Sieminska *et al.*, (2010).

The correlation study between adiponectin and each of BMI and & WHR, showed no significant correlation either in group H or group SH. These results could be attributed to BMI and WHR in the subjects in this study were in normal range. Arita *et al.*, (1999) revealed that in human, adiponectin levels were found paradoxically to be decreased in obese only, compared with normal individuals, making it the only known adipocyte-specific hormone that is down-regulated in obesity.

The current study, reported a significant increase in IL-6 and IL-15 serum levels in the Hashimoto's patient three groups as compared to the control group. Also, a significant positive correlation was found between IL-6 and IL-15 in the three patient groups. Ruggeri *et al.*, (2006) and Matsumura *et al.*, (1999) agreed with our results as they stated that different cytokines released by immune cells cause thyroid cell damage and are involved in inflammatory processes. This finding suggests that IL-6 and IL-15 are involved in the development of the disease in the different thyroid function status. Taddei *et al.*, (2006) explained that the chronic activation of the immune system due to HT can lead to impaired endothelium dependant vasodilatation and may cause endothelial dysfunction in humans and IL-6 promotes atherogenesis directly by endothelial-dependant mechanisms and indirectly by stimulating hepatic production of C reactive protein. Also regarding IL-15, Bigalke *et al.*, (2009) stated that IL-15 is a proinflammatory cytokine that is present in a broad variety of tissues and cells. It

causes a stimulation of T cell and B cell proliferation and activity whereas IL-15 particularly promotes the proliferation and survival of natural killer cells (Bulanova *et al.*, 2001). Natural killer cells are bone marrow-derived granular lymphocytes that, without previous sensitization and restriction by major histocompatibility proteins, are cytotoxic against malignant and virally infected cells (Dunne *et al.*, 2001).

Furthermore, no significant correlation was observed between adiponectin and IL-6 or IL-15. Rovin and Song, (2006) and Sieminska *et al.*, (2010) disagreed with these results as they stated that the adipokine possesses anti-inflammatory properties although recent studies have documented pro-inflammatory and immunomodulatory effects. They explained that adiponectin activates pro-inflammatory transcription factor NF- κ B and ERK1/2MAPK and influences immune responses by regulating T cell activation and suppressing B cell development. They added that the interplay between adiponectin and immune cells plays a role in the development of autoimmune diseases, and in these states, adiponectin correlates with increased serum levels of leptin and IL-6. Also Quinn *et al.*, (2009) observed that IL-15 is a cytokine that is highly expressed in muscle tissue and it has a relation with the adipokine as it act as a circulating myokine that inhibits adipose tissue deposition. The results in this study might be attributed to the patients who were selected with normal weight and normal BMI.

From the results of the current study, we concluded that, IL-6 and IL-15 serum levels may be involved in the pathogenesis of Hashimoto's thyroiditis whatever thyroid function status; however, serum adiponectin may have no role. Future studies are recommended to find its exact role in disease monitoring.

Theoretical Study of the Tautomeric Preference and Self Association Processes of 2-Pyrrolidinone

Ahmed M. El Defrawy*, Maii S. Mashaly, Mamdouh S. Soliman

Department of Chemistry, Faculty of Science, Mansoura University, Mansoura, 35516, Egypt.

*ameldefrawy@mans.edu.eg

Abstract: Relative tautomerization energies, dipole moments for the tautomers of 2-pyrrolidinone was studied by quantum-chemical calculations, using the B3LYP level of calculation with the 6-311G(d,p) basis set in the gas phase with full geometry optimization. Entropies, enthalpies and Gibbs free energies for the tautomerization process of 2-pyrrolidinone was obtained using the RHF/6-31G(d) level of computation. The calculations showed that, the Keto form is the most stable form in the gas phase. The entropy effect on the Gibbs free energy change of the tautomerization process 2-pyrrolidinone is found to be very small, and has practically no significance for the tautomeric equilibria of the 2-pyrrolidinone. The enthalpic term is dominant in the determination of the equilibrium constant. The ability to form dimer, trimer and tetramer was investigated concerning the energetical changes; dipole moments using the RHF/6-31Gd level of computation. The thermodynamic parameters at different temperatures were studied using the PM3 semiempirical method. The results showed that, there is a high interconversion process between the cyclic and open dimer. Also, the probability to form higher association forms is presumably rare. At room temperature 2- pyrrolidinone only could exist in a dimer form in equilibrium with the monomer. The results are in good agreement with the available experimental data.

Key words: 2-pyrrolidinone, tautomerization, self association, thermodynamic Parameters, theoretical calculations.

1. Introduction

The experimental studies on tautomerism still a challenging task, because most of the tautomers are not observed in the experimental studies due to their low concentration. So, the theoretical investigation of tautomers is meaningful. 2-pyrrolidinone (2-py), is a saturated cyclic five membered ring molecule, which has the peptide moiety HN-C=O containing an acidic NH proton and a basic C=O group, that can act as a hydrogen bond donor and hydrogen bond acceptor with the expected hydrogen bonding interactions. The protropic tautomerism of these 2-pyrrolidinone, results from the migration of liable hydrogen from the ring nitrogen or oxygen atom, hence the 2-pyrrolidinone can exist in keto - enol tautomeric forms.

Knowing the relative stabilities of the various tautomeric forms of a molecule is not only important for chemical research but also the fundamental for biological research [1-2].

The proton attached to the Nitrogen atom (N1) in the 2-py molecule, is responsible for its interaction with different molecules through hydrogen bonding.

Several experimental studies have been conducted on the self association of 2-pyrrolidinone molecule [3-7]. Although theoretical calculations were proved to give good results for thermodynamic properties [8-10], little attention has been paid to the influence of temperature on tautomerization process, and no theoretically thermodynamic studies at different temperatures were reported [11].

Hydrogen bonding and proton transfer have been studied in great detail both experimentally and theoretically [12-14]. Substantial progress has been achieved in the elucidation of the detailed mechanism of proton transfer in small molecules using high-level ab initio quantum mechanical theory [13, 15, 16]. However, the ab initio approach becomes prohibitively expensive in terms of computer resources and time when dealing with large organic molecules or molecular associations. Therefore, it is of considerable interest to study the applicability of semi empirical methods for the confident prediction of hydrogen bonding interactions. The semi empirical method, namely PM3, describes the energetics and topographies of hydrogen-bonded systems fairly accurate [17, 18]. Accordingly, we present here the results DFT and RHF calculations for the proton transfer process, as well as the RHF/6-31Gd and PM3 methods of calculations, for studying the ability to form dimer, trimer and tetramer, concerning the energetical changes and the thermodynamic

parameters at different temperatures, respectively, for depth comprehension of these formation processes.

2. Methods of Calculations

All of the calculations have been performed using the Hyperchem 8.0 program [19]. The molecular stability as well as a thermodynamic study of the keto- and enol- tautomeric forms, were theoretically investigated using the B3LYP and RHF level of computation using the 6-311G(d,p) and 6-31G(d) basis sets, respectively. For studying the self association process of 2- pyrrolidinone, the RHF /6-31G(d) method was used for the geometry optimization and for the dipole moment, the length of the hydrogen bond formed as well as the energies of the different associated forms without any geometrical constraints. The semi empirical PM3 method was used for the thermodynamic studies on the self associated forms of 2-pyrrolidinone molecule. The vibrational frequencies were calculated to confirm all stationary points. The thermodynamic parameters were calculated at (300-500) K temperature range.

3. Results and Discussion

3.1. Tautomerization of 2-pyrrolidinone

The complete transfer of the acidic hydrogen attached to nitrogen to the basic Oxygen atom of the ketonic group in the same molecule, lead to the formation of the 2-pyrrolidinone tautomeric form, and an equilibrium state between the keto and enol tautomers could be established.

Two possible conformations of 2-pyrrolidinone could be expected. A one-dimensional potential energy scans were performed to determine the most stable structure, where the torsion angle $N_1-C_2-O_6-H_7$ is changed in the range of -180 to 180° , starting with the O-H Cis conformation to the nitrogen atom ($\angle N_1-C_2-O_6-H_7 = 0^\circ$) and with 20° angle increment, applying the B3LYP/ 6-311G(d,p) method (Fig. 1). As seen in Fig. 1, the energy profile shows local minimum at about -180° and 180° and a global minimum at 0° , corresponding to the cis form which is more stable than the trans form by about 6.2 Kcal/mol.

The calculated optimum energies of the two tautomers and that of the transition state of 2-pyrrolidinone, and some geometrical parameters for the transition state are shown in Table 1 and Fig. 2, respectively.

As indicated in Table 1, the keto form is found to be more stable and has a lower binding energy by about 8.5 Kcal/mole than the enol form. The conversion process from keto to enol form requires an energy barrier of about 66.9 Kcal/mole. Also, from Table 1, one can see that the ring twisting angle

in the keto and enol forms are 25° and 17° , respectively. This gives an indication that the proton transfer process results in a decrease in the ring twist angle, and this explains the lower stability of the enol form. The dipole moment (μ), is an important tool which can be used to show the charge distribution in a molecule, and it is one of the properties often used to rationalize the structure of many chemical systems [20]. Thus, by comparing the calculated dipole moment values, 4.134 and 1.264 Debye, for the optimized structures of the keto and enol tautomers respectively, with the experimentally measured value for the monomeric 2-pyrrolidinone (3.96 Debye) [21], a strong evidence for the existence of the 2-pyrrolidinone molecule in the keto form rather than the enol form can be supported.

After the stationary points were located, vibration frequencies were calculated in order to ascertain that the structures found corresponds to minima on the potential energy surface. Based on the vibrational analysis, the changes of the thermodynamic properties: Change in free energy G , change in enthalpy H , change in entropy S , as well as the equilibrium constant(K) as a function of temperature for the keto-enol conversion process, were theoretically determined from the results of electronic, vibrational and electronic components using the RHF/6-31G(d) level of calculation, for the tautomerization process with the temperature ranging from 300 to 500 K (Table 2). Plot of the relations between equilibrium constant (K) and the absolute temperature (T) is shown in Fig.3.

With a correct application of the equation $G = -RT \ln K$, the value of the equilibrium constant K which represent the expected ratio of 2-pyrrolidinone to the 2-pyrrolidinone has been found to be of a value less than 1.45×10^{-7} at room temperatures (Table 2). This indicate the predominance of the keto form of 2-pyrrolidinone at room and lower temperatures. As observed in Fig. 3, the presence of the enol form increased by increasing temperature, but, even at 500°C the ratio enol to keto form is not expected to exceed 10^{-4} , which is relatively a very small ratio. In addition to that, the entropy effect on the Gibbs free energy change of the tautomerization process is very small (Table 2), and has practically no significance for the tautomeric equilibria. Thus, the enthalpic term is found to be dominant in the determination of the equilibrium constant.

3.2. Self-association of 2-pyrrolidinone and Temperature effect

The acidic NH proton and the basic C=O groups, in 2-pyrrolidinone molecule, permit the possible self-association via hydrogen bonding ($-C=O \dots H-N$) to be expected [22, 23]. Association

may take place between two or more molecules to form open linear dimers, cyclic dimers, open linear trimers, cyclic trimers and open and cyclic tetramers. However, higher degrees of association to form higher polymeric structures are also expected. Other type of association, which is described as a kind of side-association of two molecules to form side on dimer could be expected [24]. Such association can occur between the N-H group of one molecule and the N-H and the C=O groups of the other molecule, where the N-H hydrogen atom of the first molecule will be hydrogen-bonded with the N-H nitrogen atom of the second molecule, and the N-H nitrogen atom of the first molecule will be hydrogen bonded with the oxygen atom of the carbonyl group of the second molecule (Fig. 4). Accordingly, we can say that we are dealing with the reversible process:

Where M represents the molecule in the monomer state, and n is the degree of association. An equilibrium state between monomer state and self-associated state are established.

The electronic structure of the different expected self-associated structures were theoretically calculated and their geometry were optimized, representing a stationary point in the potential energy curve using the RHF /6-31Gd level of computation. The binding energies, hydrogen bond distance and the dipole moments of the different associated form of the 2-pyrrolidinone molecule are depicted in Table 3. On the other hand, geometry optimization of the side on self-association dimer (Fig 4) did not show any stationary point in the potential energy curve, and the structure is rapidly converted to cyclic dimer structure. This indicated that such kind of association does not represent a stable association form in case of 2-pyrrolidinone.

To the best of our knowledge, there is a lack in the study of the temperature dependence of the self association of 2-pyrrolidinone. Thus, the thermodynamic parameters of the conversion processes, H, G, and S as well as the equilibrium constant K as a function of temperature, were calculated from the results of quantum mechanical calculations of electronic, vibrational, rotational, and translational energy components, and the estimated entropy at different temperatures using the PM3 level of computation. The relation between the equilibrium constant K and temperature for the conversion between monomer and both expected cyclic and open dimeric, trimeric and tetrameric associated forms, are shown in Figs. 5, 6, 7.

From the results of this thermodynamic study, it can be seen that the conversion process of 2-pyrrolidinone in its cyclic trimer state to the open

linear trimer state, as well as the conversion for the cyclic tetramer state to the open linear tetramer state is highly increased as the temperature increase (Figs, 6 and 7). Moreover, by comparing the equilibrium constant values for the conversion process for these higher associations at room temperatures (less than 10^{-4} mol/l), one can predict that there is no existence of the higher polymeric structures such as trimers or tetramers in the association model.

From previous experimental studies [5-7], it was reported that, at low concentration of 2-pyrrolidinone, the dominant species will be the cyclic associated dimer (with zero dipole moment), in addition to the open dimer is present with small amounts. For the conversion process of 2-pyrrolidinone from the cyclic dimer to the open linear state, the K values is highly increased as the temperature increase (Fig.5-c). This indicated that as the temperature increase, this favors the conversion of 2-pyrrolidinone from the cyclic dimer to the open dimer. Since the dipole moment value is a very useful tool to deduce the structure of a molecule [20]. Thus, by comparing the experimentally determined dipole moment value (2.30 D) from the nonlinear dielectric spectroscopic study [21], with the calculated values for the cyclic and the open associated forms (Table 4), one can predict that, the higher measured value for dipole moment for the dimer (more than zero and lower than 4.13 D) indicates the very rapid inter conversion between cyclic and open associated structures.

Also, it worthy to notice that, the binding energies of the cyclic and open dimer, are 13.5 kcal/mol and 8.7kcal/mole, respectively. These values when compared with experimentally determined dissociation energies of the water dimer [25], which give an indication that, the hydrogen bonding interaction in 2-pyrrolidinone is moderate. Moreover, the G values for both dimers (Table 3) increase with the increase of the temperature, indicating that the interaction weaken as the temperature increase. From Table 5, it can be noticed that, the enthalpy change in the conversion process from the cyclic to open dimer is an endothermic process. In addition to that, the value of the equilibrium constant is high enough to raise the probability of the existence of the open dimer at room temperature, which support the idea of rapid their conversion [25].

As observed from the previous results, one can conclude that, the association process to form cyclic or open species must be considered not only a factor of energy, but also a factor of the thermodynamic parameters of the equilibrium process.

Table 1: Calculated energies and dipole moment of tautomers and its transition states using B3LYP 6-31G(d,p) calculations.

Conformation	Total Energy (K Cal/mol)	Dipole Moment (Debye)	Ring twist angle
Keto	-179802.82	4.134	25
Enol	-179794.29	1.264	17
Transition state	-179735.95	3.343	21

*mgeelghalban@mans.edu.eg

Abstract: In this work optimal working conditions were established for the determination of trace levels of lead on hanging mercury drop electrode with Ammonium pyrrolidine dithiocarbamate (APDC) as a preconcentrating agent in acetate buffer media using square wave anodic stripping voltammetry. The optimized experimental conditions include pH, APDC concentration, accumulation time, accumulation potential, scan rate, pulse amplitude and SW frequency on the voltammetric response were studied. A linear relationship between the peak current and lead concentration was obtained over the range (5-40 ppb) with correlation coefficient of 0.99911. Detection limits of 0.89 ppb was obtained with standard deviation of 0.03706. The interference by metal ions which are of great significance in real matrices have been studied. The formation of complex formed between lead and APDC was investigated using both of SWASV and cyclic voltammetry technique. The method was successfully applied for the determination of lead in tap water samples.

Key Words: Lead, APDC, Square wave, Cyclic Voltammetry, tap water

1. Introduction:

Lead is a ubiquitous environmental pollutant with no known biological function. It exhibits severe deleterious effect on human [1] that has strong chemical toxicity at low concentrations. It can occur as a result of industrialization in the production of pigments, anticorrosion coatings, lead smelter, alloys, and batteries, causing significant disturbances in air, dust, soil, water, sediments, food, etc. The world health organization (WHO) and the US environmental protection Agency (EPA) have set maximum levels of 50 and 10 $\mu\text{g l}^{-1}$ of Pb in sea water and drinking water, respectively [2,3]. Exposure to high levels of trace metal ions (e.g. Cd(II), Pb(II), Cu(II), and Hg(II)) causes a variety of health problems, because they tend to accumulate in the body, and have low rate of clearance [4,5]. Therefore, it is critical to minimize the exposure of humans to these contaminants and this can be ensured through effective water quality monitoring.

As we all know lead is one of the most abundant heavy metals and its toxic effects cause environmental and health problems because of its stability in contaminated sites and complexity of mechanism in biological toxicity, particularly dangerous for children leading to mental retardation when exist with abnormal concentration in body fluid [6]. Lead ions can also interfere directly with calcium signaling, since it has a similar ionic radius to Ca^{2+} and hence the ability to substitute for calcium [7].

Several analytical techniques are available for quantification of lead such as atomic absorption spectrometry (AAS) [8], inductive coupled plasma mass spectrometry (ICP-MS) [9], inductive coupled plasma atomic emission spectrometry (ICP-AES) [10], high performance liquid chromatography [11], capillary electrophoresis [12], backward line scattering [13], and anodic stripping voltammetry (ASV) [14]. Among these methods, adsorptive stripping voltammetry (AdSV) is commonly employed because of its wide linear dynamic range and low detection limit which achieved as the result of performing the preconcentration steps directly into the voltammetric cell, thus decreasing the sampling handling, risk of sample contamination, and multi-element analysis capacity. An additional advantage of AdSV over other methods is the simplicity of the instrumentation, which is relatively inexpensive, small in size, requires low levels of electrical power and is sufficiently portable to permit its use in the field. Also possibility of analyzing various samples without the need of a prior separation is also convenient. Thus, adsorptive stripping analysis [15-17] is becoming a widely accepted tool for trace amount measurements of heavy metal ions. The history, theoretical background and application, of AdSV are given in references [18-21]. AdSV is widely used for individual and simultaneous determination of heavy metals and many reports on the application of AdSV for the determination of lead were listed [22-25]. The mercury film electrode (MFE)

[14] and the hanging mercury electrode (HMDE) [26] have been traditionally used for ASV because of the advantageous analytical properties of mercury in the negative potential range. So the aim of this work is to find a new procedure to determine the concentration of the lead using a APDC on HMDE using anodic stripping voltammetry .

2. Experimental:

2.1. Apparatus:

A Metrohm 693 VA processor with a three electrode system consisting of a hanging mercury drop electrode (HMDE) as the working electrode, Ag/AgCl reference electrode and a platinum counter electrode were used to obtain the voltammograms. A hanna 211 pH meter was used to determine the pH of solutions.

2.2. Reagents:

Ammonium pyrrolidine dithiocarbamate (Analar, BDH) was dissolved in absolute ethanol give 10^{-2} M stock solution. Stocks solution of lead (1000 mg l^{-1}) was prepared by dissolving 0.1598g of lead nitrate in deionized water and diluting to 100 ml in volumetric flask. Standard solutions of Pb(II) or ligand with lower concentrations were prepared daily by diluting the stock solutions. Acetate buffer was prepared by dissolving 13.6g of sodium acetatetrihydrate in deionized water and diluting to 1.0 L. Appropriate volumes of this solution were adjusted to the required pH with glacial acetic acid.

2.3. Procedure:

The general procedure adopted for obtaining square wave adsorptive stripping voltammograms was as follow:

The supporting electrolyte solution (10ml acetate buffer pH 3.5) containing $3 \mu\text{mol/L}$ was pipette into the cell and purged with nitrogen for 7 min. the deposition potential (-0.35V vs. Ag/AgCl) was applied to fresh mercury drop while the solution was stirred for 180sec. At the end of deposition time the stirrer was switched off, and after 10 sec had elapsed to allow the solution to become quiescent, the potential was scanned in a positive direction from -0.3 to 0 V using square wave adsorptive stripping Voltammetry, with a scan rate of 60 mV/sec. , Modulation frequency 160 Hz and a pulse amplitude of 50mV each scan was repeated three times with a new drop for each analyzed solution and the mean value was obtained.

After back ground stripping voltammograms had been obtained, an aliquot at the Pb(II) standard was introduced into the cell and following the described procedure, the sample voltammogram was achieved, lead peak was registered at about -0.35V ,

and its current was used as a measure of lead concentration all equipments were carried out at room temperature.

3-Results and Discussion

3.1 Effect of operational parameters:

3.1.1. Effect of pH variation:

The effect of the solutions pH on peak current (Fig. 1) of the Pb-APDC complex was studied in the 3.0 – 6.0 range. C_{pb} and C_{APDC} were 20 ppb and $3.1 \mu\text{mol l}^{-1}$, respectively ($E_{\text{acc}}:-0.45\text{V}$, $t_{\text{acc}}:60\text{s}$). It is clear that peak current of the Pb-APDC complex is maximum at $\text{pH} = 3.5$ and decreases rapidly after $\text{pH} 3.7$. Greater pH values cause a decrease in the peak current and the signal is very broad probably due to the diminished complexing ability of the ligand at such pH values, so pH value of 3.5 was chosen for the whole study.

Fig.1: Influence of pH on the peak current of the Pb-APDC complex. Conditions: Pb(II): 25 ng/ml ; $C_{\text{APDC}} : 3 \mu\text{M}$; $E_{\text{acc}}:-0.45\text{V}$; $t_{\text{acc}}:60\text{s}$; scan rate 20 mV/s ; pulse amplitude : 20 mV ; and frequency: 50 Hz .

3.1.2. Effect of APDC concentration (C_{APDC}):

The influence of the ligand concentration on the peak current (Fig.2) was studied with APDC concentration in the range of ($0.1 \mu\text{mol l}^{-1}$ - $4.4 \mu\text{mol l}^{-1}$) for pb(II) 20 ng/ml , while other standard measuring conditions remained constant ($\text{pH} : 3.5$; $t_{\text{acc}} :60\text{s}$; $E_{\text{acc}} -0.45\text{v}$)

The results show that by increasing the ligand concentration the peak current increase (as expected) showing that peak current is strongly depend upon the ligand concentration. For higher concentration $4.4 \mu\text{mol l}^{-1}$ a slight decrease in the peak current was observed this effect may be due to the competitive adsorption of APDC with the complex form. An optimum APDC concentration of $3.1 \mu\text{mol l}^{-1}$ was selected for farther studies.

Fig.2: Influence of C_{APDC} on the peak current of the Pb-APDC complex.

Conditions:Pb(II):20ng/ml; pH3.5; E_{acc} :- 0.45V; t_{acc} :60s;scan rate 20mV/s; pulse amplitude :20mV ;and frequency:50Hz.

3.1.3. Effect of accumulation potential:

Fig.3 shows the variation of accumulation potential between -0.6 to -0.1 V with the optimum reagent concentration and other standard measuring conditions remained constant (pH: 3.5; C_{APDC} : $3.1\mu\text{mol l}^{-1}$, t_{acc} : 60s).

The peak current extremely increase from -0.1 to -0.35 v due to increase in the accumulation of Pb-APDC on the surface of the electrode. A decrease in peak current is observed by changing potential from -0.4 to -0.6 v. An accumulation potential of -0.35 V gives the best sensitivity and was chosen for subsequent work. More negative potential values cause electrolysis of Pb(II). Also this decrease in peak current may be due to the adsorption of the ligand on the electrode surface, and thus, cause decrease in the ligand concentration.

Fig. 3: Influence of E_{acc} on the peak current of the Pb-APDC complex.

Conditions:Pb(II):20ng/ml ; pH 3.5; C_{APDC} 3 μM ; t_{acc} :60s; scan rate 20mV/s; pulse amplitude :20mV ;and frequency:50Hz.

3.1.4. Effect accumulation time:

The extent of preconcentration depends on the length of time over which the adsorption is allowed to proceed. The longer the accumulation time, the more pb(II) APDC complex is adsorbed and the larger the peak current observed. The peak current increase almost linearly at first and then curve slightly toward the time axis up to 270 sec, (Fig. 4). Such time dependant profiles represent the corresponding adsorption isotherms, the choice of accumulation time requires a trade-off between sensitivity, speed and selectivity. Thus 180 sec was selected to comprise between sensitivity and speed .Also 180 sec. give sharp peak after this time a broader peak is obtained.

Fig. 4: Influence of t_{acc} on the peak current of the Pb-APDC complex.

Conditions:Pb(II):20ng/ml ; pH 3.5; C_{APDC} 3.1 μM ; E_{acc} :- 0.35V; scan rate 20mV/s; pulse amplitude :20mV ;and frequency:50Hz.

3.2 Effect of potential sweep conditions:

3.2.1. Scan rate:

The potential scan rate for SW-AdSV procedure was tested in the range between 2 and 80 mV/sec. and the stripping peak current that was obtained showed a linear dependence on the scan rate (Fig. 5). This linear behavior may suggest that the peak current comes largely from surface adsorbed species [27].

In this work, a potential scan rate 60 mV/sec was chosen and used in all experiments.

3.2.2. Square wave frequency :

The peak current of pb-APDC increased when the frequency increase from 30 to 160 Hz (Fig. 6) and it was concluded that in order to assure maximum peak and more sensitive peak, 150 Hz square - wave frequency was the ideal choice for this operational parameter.

Fig. 5: Influence of scan rate on the peak current of the Pb-APDC complex.

Conditions: Pb(II):20ng/ml ; pH 3.5; C_{APDC} 3.1 μ M; E_{acc} :-0.35V; t_{acc} :180s; pulse amplitude :20mV ;and frequency:50Hz.

Fig. 6 Influence of frequency on the peak current of the Pb-APDC complex.

Conditions: Pb(II):20ng/ml ; pH 3.5; C_{APDC} 3.1 μ M; E_{acc} :-.35V; t_{acc} :180s; scan rate:60mv/sec ; pulse amplitude :20mV.

3.2.3. pulse amplitude :

Varying the value of excitation wave pulse amplitude (Fig. 7) plays an important role for the measured peak current increasing this parameter over the range 10-50 mV, resulted in extremely enhancement of the voltammetric peak current. As a result 50 mV were adopted as optimum for pulse amplitude.

3.3 Analytical parameters:

Once the most ideal and suitable chemical conditions and instrumental parameters for the stripping voltammetric determination of lead metal

ions were established, calibration plot for this metal ion was recorded to estimate the analytical characteristics of the developed square wave adsorptive stripping voltammetry method.

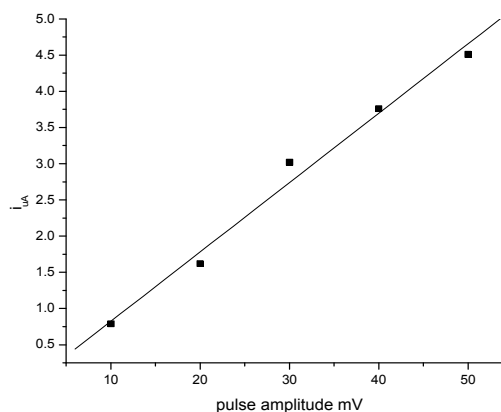

Fig. 7: Influence of pulse amplitude on the peak current of the Pb-APDC complex.

Conditions: Pb(II):20ng/ml ; pH 3.5; C_{APDC} 3.1 μ M; E_{acc} :-0.35V; t_{acc} :180s; scan rate 60mv/sec ; frequency 160Hz.

3.3.1. Calibration graph and detection limit:

The calibration graph (Fig.8) for the determination of lead was obtained under the optimized conditions. The pH : 3.5; C_{APDC} : 3.1 μ mol l^{-1} ; t_{acc} : 180 s ; E_{acc} : -0.35 V. C_{APDC} is 3.1 μ mol l^{-1} , adsorptive curves of pb (II) at concentrations from 5 to 40 ng/ml produce a linear calibration plot ($R=0.99911$) . The precision expressed as the relative standard deviation (RSD) was 0.31535 % for nine successive measurements of the same sample containing 20.0 ng/ml of pb (II). The limit of detection (LOD) is equal to three times the standard deviation of the blank peak current divided by the slope of the calibration curve $3s_b/m$ is equal to 0.89 ng / ml.

3.4 Influence of other metal ions:

To evaluate the selectivity of the method, the influence of many ions on the determination of Pb(II) was examined in the presence of optimum reagent concentration 3.1 μ mol l^{-1} and 20 ng/ml Pb(II). In adsorptive voltammetry interference may arise from competitive adsorption of the ions and their complex or from reduction in the vicinity of the analyte peak the major sources of interference are likely from co-existing metal ions capable of forming complexes with the used chelating agent, hence, affecting SW-AdSV response via an over lapping peak or competing for adsorptive sites on available

ligand. The effect of the following ions, which is of great significance in industrial or environmental matrices, was tested at the optimal experimental conditions. The results of this study on the lead APDC reduction peak are summarized in Table 1.

Table 1: Effect of interfering species on the lead-APDC reduction peak.

Substance added	Concentration (ppb)	Change in i_p %
Zn ²⁺	1000	-4.76
Sr ²⁺	10000	-1.11
Fe ³⁺	3000	-9.31
Ni ²⁺	1000	-13.9
Cd ²⁺	400	-7.06
Cu ²⁺	40	-3.85
Hg ²⁺	100	+2.94
PO ₄ ³⁻	10000	-4.01
HCO ₃ ⁻	10000	-9.29

F ⁻	800	-1.7
Br ⁻	400	-2.8
Cl ⁻	400	-1.1

Fig.8: Calibration curve at optimum condition.

3.5 Evidence of complex formation:

Both square wave voltammetry and cyclic voltammetry have been utilized to elucidate and confirm the possible complexation reaction which can occur between lead and ammonium pyrrolidine dithiocarbamate.

Fig. 9 shows an evidence of complex formation between Pb and APDC using square wave voltammograms, this was established as result of tracking the addition of APDC to Pb which produces a series of overlapping signals. Two peaks predominate where one corresponds to a reduction process of free (labile) Pb²⁺ (E_p at -0.36V), this peak current decrease and shifted to more negative potential with the addition of ligand. This behavior may be attributed to the fact that Pb atom is restricted

by two moles 1:2 stoichiometry of the ligand [28-29], so energy is required to reduce such restriction in the complex formed. On the other hand, a new peak is formed (at more positive potential) and its height increase with the addition of the ligand, this peak is related to the reduction

Fig. 10 shows cyclic voltammograms as an evidence of complex formation between Pb and APDC in 0.1 M acetate buffer solution of pH 3.5. As seen from Fig. 10-a, there is an oxidation and reduction peak for APDC at -0.53V and -0.34V which disappear upon the addition of the metal. Pb²⁺ shows reduction and oxidation peaks (Fig.10-c) at -0.40 and -0.35V, respectively which decrease by adding the ligand. A new peak appears at -0.134 and -0.146 V at the same conditions (Fig.10-b) where the Pb-APDC complex formed as a new species.

Fig.9: Square wave voltammogram of 20ng ml⁻¹ Pb (II) with different concentrations of APDC

Fig. 10: Cyclic voltammograms of a: 5x10⁻⁴ mol l⁻¹ APDC ,b: 5x10⁻⁴ mol l⁻¹ APDC + 30mg l⁻¹ Pb(II), c: 30mg l⁻¹ Pb(II). pH 3.5,scan rate 500mVsec.⁻¹

3.6 Application:

The utility of the developed method was tested by determining lead in some synthetic mixtures (Table 2) which give good recoveries. The proposed procedure was successfully applied for the determination of the concentration of lead metal in tap water sample by SWASV technique. The sensitivity was calibrated by standard additions to the sample and the initial metal concentrations were calculated by extrapolation. Consequently, linear calibration range was automatically obtained as being related to quantitative mode of the voltammetric unit. As can be seen from Fig.11, the current of the oxidation peak of lead increased by the addition of the standard solution. The concentration of Pb (II) in tap water of Mansoura city (Egypt) was found to be 25 ng ml⁻¹. This value is in the limit values according to TSA, WHO, EPA [30,31].

Table 2 : Determination of Pb(II) 20 ng ml⁻¹ in some synthetic mixtures.

Mixture number	Synthetic mixtures	Recovery
Mixture (1)	NO ₃ ⁻ , PO ₄ ³⁻ , Cl ⁻ , HCO ₃ ⁻ , CO ₃ ²⁻ , F ⁻ , Br ⁻	99%
Mixture (2)	Zn ²⁺ , Fe ³⁺ , Sr ²⁺ , Ni ²⁺	106%

Abstract: The paper aims to examine gender differences in financial literacy among college students. Using the stratified sampling method, 2,340 college students from six public and five private colleges were studied. The findings indicate gender differences in different dimensions of financial literacy, in which males were more knowledgeable in financial matters than female students. The results revealed that among the six dimensions of financial literacy, male students have more knowledge concerning credit and risk management, while females are more knowledgeable in respect of general financial literacy. [Leila Falahati, Gender Differences in Financial Literacy among College Students. Journal of American Science 2011;7(6):1180-1183]. (ISSN: 1545-1003). <http://www.americanscience.org>.

Keywords: Gender, Financial Literacy, College Students, Financial Education,

1. Introduction

Gender issues have received considerable attention in statements concerning economics and finance in recent decades. Since gender differences have been observed in a number of financial domains, such as behavior, investment and, perhaps, most importantly, in financial skills, gender issues have become a concern among economists and gender educators. Scholars have documented gender differences in financial affairs such as financial literacy, attitudes and particularly financial behavior.

Prior studies have determined that financial literacy has important implications for financial behavior. However it is widespread among researchers that people with low financial literacy are more likely to have problems with debt (Lusardi and Tufano, 2009b), lower level of wealth management (Hilgert et al., 2003), and, most importantly, a lack of retirement planning (Lusardi et al., 2009a). Lusardi (2010) indicated that financial literacy is the main component of financial decision-making, and many young people desire more financial literacy.

Young adults, particularly college students, receive more attention from financial educators (Goldsmith and Goldsmith, 2006; Gutter et al., 2010; Hayhoe et al., 2000; Hira et al., 2000; Joo, 2008; Norvilitis et al., 2006), as they have easier access to financial sources such as credit, debt and educational loans than previous generations of students. However, because of the lack of financial management skills and poor money management, students report greater financial problems, greater stress, as well as decreased financial well-being (Hayhoe et al., 2005; Hira and Mugenda, 2000; Kidwell and Turrisi, 2004; Norvilitis, et al., 2006).

In terms of financial literacy, college students showed an extensive gender disparity (Barber and Odean, 2001; Goldsmith and Goldsmith, 2006). Garman and Fogue (2006) pointed out that financial literacy is a fundamental tool in successful financial management. However, the research findings indicate that female students consider themselves as being less knowledgeable about financial topics (Hira and Mugenda, 1999), financial analysis (Webster and Ellis, 1996) and investing (Goldsmith and Goldsmith, 1997). In comparison to men, recent studies have also found that women are less knowledgeable financially (Goldsmith and Goldsmith, 2006).

To aid young adults, particularly college students, it is crucial to understand their level of financial literacy and, most importantly, understanding gender differences in financial literacy would provide more knowledge about students' financial needs. Furthermore, since college students are the future labor force contributors, it is necessary to understand the financial needs and dilemmas of males and females in conducting their finance during college life. Most importantly, the lack of financial literacy may lead college students to become involved in a higher level of financial problems during college life, which has a significant effect on their present and future family, and career life.

2. Materials and Methods

2.1 Instrumentation

Financial literacy knowledge was measured by an instrument developed by Sabri et al., (2006) based on the Malaysian context. The instrument consisted

of 25 true and false questions concerning financial goals, financial records, savings, investment, retirement, banking system, time value of money, wills, insurance, education loan, and general knowledge on personal finance. However, finally, the components comprised six dimensions including: general knowledge, investment, savings, record, credit, insurance and risk management. The total score for financial knowledge and the six dimensions was computed by summing the correct answers for 25 questions.

2.2 Sample procedure and sample profile

Data were collected using the stratified sampling method at six public and five private universities across Malaysia. A self-administered questionnaire was used as the data collection methodology. Of the 2,500 students who responded to the survey, 40.4% were male and 59.6% were female students; 71.4% were Malay being the major ethnic group in Malaysia, 21.7 % were Chinese, 5 % were Indian and others (.8%). The mean age of the respondents was 21 years. Students from public universities were 60% while others, 40%, studied in private universities.

2.3 Data Analysis

To determine gender differences in financial literacy the mean comparison t-test was conducted between male and female students.

3. Results and Discussions

The results of the t-tests presented in Table 1, revealed that there were statistically significant differences between male and female students in the financial literacy score and some of its components. The results revealed that male students ($M= 12.61$) have a higher level of financial literacy than female students ($M= 12.21$). Assessment of financial literacy components indicated that female students ($M= 3.69$) have a higher level of knowledge in general issues than male students ($M= 3.63$). The findings indicated that the mean comparison for general knowledge was statistically significant, $t=-1.023$ $P\leq .00$.

Table 1: The Result of the t-Test for Financial Literacy

Items	Male	Female	t	Sig
Financial Literacy	12.61	12.21	2.58	.00
General	3.63	3.69	-1.023	.00
Credit	2.17	1.91	5.75	.00
Record	.940	.949	-.386	.696
Saving	3.071	3.075	-.073	.942
Risk management	1.57	1.43	3.56	.000
Investment	1.2	1.13	1.807	.071

**df*:2338

Male students have a higher level of knowledge concerning credit ($M= 2.17$) while females have a lower level ($M= 1.91$) and, in addition, male students have a higher level of knowledge of risk management ($M= 1.57$) than female students ($M= 1.43$). The findings of the t-test analysis indicated statistically significant differences for credit knowledge, ($t= 5.75$, $P\leq .00$) and for risk management, ($t=3.56$, $P\leq .00$) between male and female students. However, although there were no statistically significant differences between male and females for records, savings and investment items the mean comparisons revealed slight differences. The mean comparisons of savings, records and investment knowledge indicated that male students have a higher level of knowledge in investment items while females have a higher level of knowledge concerning records and savings.

These findings indicate that male students are more knowledgeable financially than female students, which is consistent with previous findings (Chen and Volpe, 2002; Eitel and Martin, 2009; Goldsmith and Goldsmith, 2006; Hira and Mugenda, 2000; Lim et al., 2003; Shim et al., 2010), and emphasizes that female students have less financial literacy than male students. Female students have less knowledge concerning credit, risk, investment and insurance (Goldsmith and Goldsmith, 2006; Hira and Mugenda, 2000), while male students are less knowledgeable in general knowledge, records and savings (Barber and Odean, 2001). The results indicate that female students are more knowledgeable concerning general issues and savings and recording, which are relevant to cash flow management, while male students are more knowledgeable regarding credit, risk and investment, which are relevant to financial planning.

4. Conclusion and Implications

The main aim of the present study was to determine gender differences in financial literacy among college students. The findings of the research indicate that male students are more knowledgeable than female students, however, among the six dimensions of financial literacy, male students have more knowledge concerning credit and risk management, and females are more knowledgeable concerning general knowledge. The findings indicated that female students have a lower level of financial literacy than male students, which may result in female students being involved in a higher level of financial problems due to the lack of proper financial skills and literacy. In addition, it should be noted that the financial socialization process is the main part of acquiring financial literacy and skills,

therefore, parents might also consider providing equal practical opportunities for sons and daughters to practice and learn financial matters.

Moreover, regarding the family sphere, schools have an important role in enhancing students' financial literacy, therefore, due to differences in male and female financial literacy there is the need to enhance schools financial literacy programs and expand practical subtitles. An efficient financial literacy program must teach not only the basic knowledge and financial techniques but also ways to enhance self-efficacy, stress management, problem solving and life skills, as well as methods for the wise and even righteous use of financial resources for both male and female students.

There are various sources that students can tap into to acquire financial knowledge, such as attending seminars, workshops, courses and even pamphlets. All of these sources can be beneficial as they help provide basic financial management knowledge and skills during college life and before the student graduates and enters the job market, thereby equipping them with the necessary skills to manage their income effectively.

It should be mentioned that since the majority of students, both male and female, after graduation, are future labor force workers, it is important to set up educational programs to educate students about financial skills and the necessities of efficient money management. Based on the present research findings it is recommended that in formulating a financial education strategy, the distinct features of financial knowledge and financial management, such as savings, insurance and risk management should be taken into consideration to meet the information needs and help educate individuals on financial matters.

In addition, it is recommended that the program provides relevant information about the financial literacy and its benefits in later lifecycles. Moreover, as there is a large proportion of females among students who perceive themselves as having a lower level of financial literacy than males, a special education program that covers financial literacy and managerial skills should be set up. This would be for the purpose of equipping females with appropriate financial skills, as they will constitute the main proportion of the labor force after graduation.

Abstract: In this research, the shear resistance parameters of mixture of reinforced sand-kaolinite were determined with random distribution of polyethylene fibers (PEF). All samples were compressed to a certain density and then the direct shear test was done. The dimensions of direct shear set were 10×10×2 cm. Different materials such as sand, Kaolinite and polyethylene were used in the experiments. In these experiments, moisture content, amount of polyethylene (PEF), fiber size and speed of shear stress were variable. Test results show that by increasing fiber ratio the shear resistance parameters of sand-kaolinite mixture increase. Also, in reinforced mixture of sand-kaolinite the shear resistance increases by increasing the speed of shear stress.

[Mahmood Ghazavi, Akbar Pashazadeh, Morteza Chekaniazar. Experimental study of the effect of polyethylene fibers with random distribution on the engineering behavior of the mixture of flimsy sand with clay soils. Journal of American Science 2011;7(6):1184-1188]. (ISSN: 1545-1003). <http://www.americanscience.org>.

Key words: Sand-Kaolinite, Reinforced soil, Fibers, Direct shear test, shear stress speed

1. Introduction

Natural soil in the project site is not always suitable to use and may cause significant settlements due to loading on poor soil. To prevent these settlements or other poor mechanical properties, specific techniques should be used to improve these properties. To increase the soil resistance, designers always use mechanical processes such as compression, drainage by sand wells and consolidation and chemical processes such as reform and stabilization by the use of reinforcing elements (Nataraja and McManis, 1997). So far, different elements such as fiber glass, zinc coating steels and polymers such as geo-textiles, the geo-grades and fibers cut from polyethylene, polyester, and polypropylene has been used to reinforce the soil (Almansa and Cánovas, 1999). Gary and Ohashi (1983) have provided a model for the soil and fibers behavior in the shear zone. They determined the amount of fiber needed for optimal conditions of shear resistance by testing a large number of sand samples reinforced with plastic and fiber plant and a copper wire in direct shear set and analyzing the results. Nataraja and McManis (1997) carried out experiments on compression, direct shear, single-axis and CBR to investigate the behavior of (steel-fibre) reinforced clay and sand by synthetic fibers, and reported an increase in shear resistance, single-axis compressive resistance and particularly an increase in the CBR. The increase in impact resistance for steel-fibre reinforced concrete has been studied in several

experiments, e.g. by Nataraja *et al.* (2005), Luo *et al.* (2000), Almansa and Cánovas (1999).

In the investigation done by Naeini and Sadjadi (2008), the waste polymer materials has been chosen as the reinforcement material and it was randomly included in to the clayey soils with different plasticity indexes at five different percentages of fiber content (0%, 1%, 2%, 3%, 4%) by weight of raw soil. CBR tests are conducted by Kalantari *et al.* (2010) and their experimental findings are analyzed with the point of view of use of waste plastic fibers in soil reinforcement. Effects of Random Fiber Inclusion on Consolidation, Hydraulic Conductivity, Swelling, Shrinkage Limit and Desiccation Cracking of Clays (Abdi *et al.*, 2008) point to the strength and settlement characteristics of the reinforced soil and compared with un-reinforced condition.

Using polymer waste in the soil reinforcement reduces these waste materials and prevents environmental degradation, which is considered as one of today's industrial problems. Therefore, in this study the waste of mineral water bottles were used. Investigating Topic History has shown that till now studies were with constant shear stress speed, but the effects of earthquake on soil has always been of importance thus in this research, the effect of increasing shear stress speed has been analyzed.

2. Material and Methods

Soil and fiber characteristics: In this study, the polyethylene fiber taken from half-liter bottles of mineral water has been used to reinforce the soil. The used soil is a mixture of loose sand and kaolinite. Characteristics of sand and kaolinite are shown in Tables 1 and 2, and figure 1 demonstrates the aggregation curve of sand.

Table 1. Characteristics of tested sand

Special weight of sand in the loose state (g/cm)	1.39
Interior friction angle of sand in the loose state (degree)	30
Density (g/cm)	2.55

Table 2. Characteristics of tested Kaolinite classification

Classification(USCS)	Plastic Index (%)	Liquid Limit (%)	Plastic Limit (%)
CH	37	58	23

3. Results and Discussion

Proctor standard density test and the results: These experiments on different mixing ratio of sand with kaolinite performed and the results represented in Table 3 shows that engineering mixture of 25 percent kaolinite and 75 percent sand, has the optimal mode.

Table 3. Density Test Results

	Amount of Kaolinite (%)	Amount of Sand (%)	Optimum moisture percentage	Maximum special dry weight (kN/m ³)
1	10	90	14.5	16.60
2	17	83	13	17.15
3	25	75	12.5	18.20
4	33	67	12.5	18.20

Direct shear test: This test used 10×10×2 cm mold on reinforced soil with three different weight percentage one, two and three and dimensions 16 × 4 and 12 × 4 mm

Direct shear test results: In this section results obtained from direct shear tests are offered.

Table 4. Direct shear test results of four different ratios of sand with kaolinite.

	Amount of Kaolinite (%)	Amount of sand (%)	Shear resistance (kPa) with 28 (kPa)vertical stress
1	10	90	21.72
2	17	83	23.30
3	25	75	31.78
4	33	67	29.56

Figure 1. Sand aggregation curve

Figure 2. Changes in shear stress on the vertical stress on mixture $4 \times 16F-K25-S75$ with different weight percentages than optimum moisture content (NF = No Fiber)

Figure 3- Changes in shear stress on the vertical stress on mixture $4 \times 12F-K25-S75$ with different weight percentages than optimum moisture content (NF = No Fiber)

Figure 5. Comparison chart of changes in horizontal displacement against shear stress on the fiber reinforced soil mixture 12×4 and naked in different scenarios optimum moisture content, dry and saturated

4. CONCLUSION

1 - The Table 4 indicated that in state 1 than 3 highest resistances to shear has been made.

2 - In accordance with the second image fibers 16×4 are observed with increasing fiber, shear resistance value of the number kPa62 mode fiber free reaches the 73 kPa with 3 percent of the fibers and shows 17 percent increase.

3 - according to the image 3 with fibers 12×4 it is observed affected by different stress, vertical Shear stress level 83 kPa reaches the number 74 kPa and it shows 15 percent increase compared to the case without the fiber with the same vertical stress.

4 - As seen in Picture 4 the highest shear resistance is in a state of optimum moisture content and the least resistance has been made in saturated state

Table 5. Results in terms of changes in shear stress on the horizontal displacement mixing $4 \times 12F2-K25-S757$ optimum moisture content in a state with a loading speed 1, 2 and 3 mm/min

	Shear stress speed (mm/min)					
	1 mm/min		2mm/min		3 mm/min	
Vertical stress (kPa)	Horizontal displacement (mm)	Shear stress (kPa)	Horizontal displacement (mm)	Shear stress (kPa)	Horizontal displacement (mm)	Shear stress (kPa)
28	10.2	35.8	10.2	37.3	11.7	38.6
56	13.2	55.13	13.2	55.13	12.9	56.2
83	14.1	71.2	13.8	72.2	14.1	72.76

5 - As seen in Picture 5 the highest shear strength with a maximum shift in the shear mode has been made in the optimum moisture content and the least resistance is in saturated state.

6 - In accordance with image 5 broken loose soils cannot be seen, but with increasing horizontal force (shear) the amount of shear stress increases to its optimal value to achieve rupture shear stress, and after reaching the maximum, whatever the shear force increased no horizontal shift is observed and the numbers remain constant maximum numbers.

7 - Results of Table 5 show the amount of shear resistance with increasing shear stress velocity shows a 10 percent increase.

8 - Generally, mixing soil and fibers with constant shear stress speed, increase friction angle and reduce adhesion.

9 - Shear resistance of soil reinforced depends on the dimensions, fibers weight percentage and vertical stress.

10- Dimensions and weight percentage of reinforces will vary in accordance with different profiles of soil.

11 - With increase in shear stress velocity, horizontal displacement in the soil sample will happen less, so samples will be broken with further stress, and shear resistance will increase.

12 - Generally, mixture saturation decreases the shear resistance.

Abstract: The paper aims to examine ethnic and gender differences in financial management among college students. Using the stratified sampling method, 2,340 college students from six public and five private colleges were studied. The findings indicate gender differences in financial management, in which female students performed greater financial management than male students. The results revealed significant ethnic differences in financial management, in which Malay students performed greater financial management than Chinese and Indian students. Keywords: Ethnic, Gender, Financial Management, College Students, Financial Education,

1. Introduction

Young adults, particularly college students, receive more attention from financial educators (Goldsmith and Goldsmith, 2006; Gutter et al., 2010; Hayhoe et al., 2000; Hira et al., 2000; Joo, 2008; Norvilitis et al., 2006), as they have easier access to financial sources such as credit, debt and educational loans than previous generations of students. However, a great body of research has documented significant gender differences in financial management (Masuo et al., 2004; Norvilitis, et al., 2006; Shim et al., 2009), the level of perceived financial problem among college students (Sabri et al., 2010) and the ethnic differences as well (McWhirter, 1997).

Financial research (Joo, 2008; Xiao et al., 2009) has long recognized that financial management is the main determinant of financial well-being, however, it is documented that one's financial management is influenced by individual and personal characteristics such as gender and ethnicity. Xiao (2008) indicated that common financial management includes practices relating to cash, credit and savings management (Xiao et al., 2006), for which effective behavior is to refer to positive or desirable behavior recommended by consumer economists as a way to reduce the level of financial problems.

The studies of financial management among college students (Borden et al., 2008; Eckel and Grossman, 2002; Knight and Knight, 2000; Lea et al., 1995; Livingstone and Lunt, 1993; Lyons, 2008) have shown that students have inadequate knowledge and skills to manage their finances. They fail to make correct financial decisions and experience a high

level of financial strain and problems such as debt load. The assessment of the research results revealed that the role of gender in financial management is unclear. For example, women are more likely to report having a budget than men (Henry et al., 2001), have more investment than men (Bajtelsmit and Bernasek, 1996) and are more likely to report using sound financial practices (Hayhoe, et al., 2000).

Conversely, others have found that women have more credit cards than men (Hayhoe, et al., 2000; Norvilitis, et al., 2006), men score higher on a test of financial knowledge (Goldsmith and Goldsmith, 1997), and women have higher levels of debt (Davies and Lea, 1995; Norvilitis, et al., 2006). However, the study of ethnic differences in financial management among college students is limited to McWhirter (1997). Generally, Malaysia is considered a multi race country with Malay, Indian and Chinese ideology, and a multicultural society with a mixture of Muslims, Hindus and Buddhists. Different ethnic backgrounds confirm the differences in ideology, life style and in turn differences in money practices.

However, the study of financial management among the ethnic groups in Malaysia is scarce. Ethnic and gender differences in financial management indicate that males and females and even different ethnic groups perform different financial management, which may have a different effect on their future life. Therefore, understanding differences in financial management provides proper knowledge concerning a student's financial needs and education to enhance their financial management.

2. Materials and Methods

2.1 Instrumentation

To measure financial management, two main dimensions including savings and spending behaviour were considered. To measure spending behaviour an instrument was developed by Sabri et al. (2006); it included 11 items requiring students to confirm whether they spent their money on those items using a Yes or No scale. Items included, mobile phone, Internet café, entertainment magazine, movies, games (Bowling, Snooker), beauty salon, cigarettes, drugs, alcohols, gambling and clubbing. Spending behaviour was computed by summing the items determined by students.

The higher the numbers of items the students spend money on, the lower the score and the lowest number of items receive the highest score. To measure saving behaviour an instrument including 5 items was adopted from Hilgert and Hogart (2002) which was concern about "saving times within six months", "saving for long term", "saving for short term" and "regarding financial condition in university, has enough money that can be put into savings". Savings behaviour was computed by summing the savings scores.

The highest score indicated good savings behaviour and the lowest score indicated poor savings behaviour. Financial management was measured by summing spending and savings behaviour; a higher score indicated safe financial management and a low score indicated risky financial management.

2.2 Sample procedure and sample profile

Data were collected using a stratified sampling method. The study sample comprised students from public and private universities; a total of 11 universities were randomly selected for the study (six public and five private universities). For each university a total of 350 students were randomly selected using the list of names obtained from each student affairs office. The total number of questionnaires distributed to the 11 universities was 3,850.

A total of 2,500 completed and usable questionnaires were returned by the students,

producing a 65% response rate. Of the 2,500 students who responded to the survey, 40.4% were male students and 59.6% were female students. The ethnic composition was Malay (71.4%), Chinese (21.7%), Indian (5.0%) and others (.8%). The age composition of students was lowest 20 years (39.3), 21-30 years (60.5%) and highest 31years (.2%). The mean age of the respondents was 20.9 years. Students from the public university were (60%) while the others (40%) study in private universities.

2.3 Data Analysis

To determine gender differences in financial management the mean comparison t-test was conducted between male and female students. To determine ethnic differences the Analysis of Variance (ANOVA) was conducted to determine the differences between three ethnics.

3. Results and Discussions

The findings in Table 1, indicated that there are statistically significant differences in financial management among the three ethnic groups ($F= 8.29$, $P\leq.00$). The results indicated that Malay ($M= 11.19$) students have greater financial management than Chinese ($M= 10.88$) and Indian ($M= 10.75$) students, however, in order of rank, Indians performed weaker financial management than the other two ethnic groups. Regarding the financial management dimension, the results depicted in Table 2, indicated that there are statistically significant ethnic differences in savings behavior ($F= 3.56$, $P\leq.00$), in which Chinese students ($M= 4.38$) have greater savings behavior, followed by Indian ($M= 3.98$) and then Malay ($M= 3.94$) students. However, there were no statistically significant differences in spending behavior between the ethnic groups.

The results of the t-tests, given in Table 2, indicate that there was a statistically significant difference in financial management between male and female students.

Table 1: The Results of ANOVA for Financial Management by Ethnic

<i>Items</i>	<i>Malay</i>	<i>Chinese</i>	<i>Indian</i>	<i>F</i>	<i>Sig</i>
Financial Management	11.19	10.88	10.75	8.29	.000
Spending behavior	3.94	4.38	3.98	3.56	.0
Saving behavior	9.11	8.96	9.04	2.21	-

The mean comparison of male and female students financial management revealed that female students ($M=11.25$) performed better financial management than male students ($M= 10.08$). This comparison was found to be statistically significant, ($t= -5.84$, $P\leq.00$). To assess financial management, the components revealed that male students have significantly better financial management ($t= 2.11$, $P\leq.00$) in savings ($M= 4.21$) than female students ($M=3.91$). The results indicated that female students spending behavior ($M=9.19$) is safer than that of male students (8.86). This comparison was found to be statistically significant, ($t= -5.27$, $P\leq.00$).

Table 2: The Result of the t-Test for Financial Management

<i>Items</i>	<i>Male</i>	<i>Female</i>	<i>t</i>	<i>Sig</i>
Financial management	10.08	11.25	-5.84	.000
Saving behavior	4.21	3.91	2.11	.000
Spending behavior	8.86	9.19	-5.27	.000

4. Conclusions and Implications

The overall findings of the present research indicated that males and females show differences in financial management, in which, overall, female students demonstrate better financial management and better spending behavior while males have better savings behavior. In respect of gender matters the findings emphasize that female students have better financial management than male students, which is consistent with the findings of Hayhoe et al. (2000). Female students spending behavior is better than male students, while male students have better savings behavior. These differences might indicate that female students are more concerned with better cash flow management (Hayhoe, et al., 2000; Henry et al., 2001) while male students are concerned about financial planning such as investment and savings. Concerning the findings pertaining to ethnicity, the present study confirmed the differences in financial management between the three ethnic groups, in which, overall, Malays performed greater financial management. In addition, the results indicated that Chinese student's performed greater saving behavior, which may be rooted in Chinese culture, in that there is greater concern for planning for investments for future life. However, there were no differences in spending behavior among the three ethnic groups.

5. Recommendations

As Malaysia is rapidly moving towards economic development, the majority of students after graduation are future labour force workers; consequently, it is important to set up educational programmes to educate students about financial skills and the necessities of efficient money management. Concerning the present research findings it is recommended that in formulating a financial education strategy, gender and ethnic differences in financial management should be taken into consideration to meet the information needs and help educated individuals in respect of financial matters.

In addition, it is recommended that the programme provides relevant information about the financial behaviour and its costs and benefits in later lifecycles. Moreover, as there were significant differences in financial management between the ethnic groups, it is recommended that a national education programme that covers managerial skills for all students is established in school. This would be for the purpose of equipping all students, beyond that of the individual ethnic and gender groups, with financial skills and proper knowledge in financial matters before leaving school and entering college life.

Histological And Ultrastructural Changes In Mammalian Testis Under The Effect Of Hydrocortisone

Waslat W. Elshennawy* and Hanaa R. Abo Elwafa

Biology and Geology Department, Faculty of Education, Ain Shams University, Cairo, Egypt

*dr-waslat@hotmail.com

Abstract: Hydrocortisone is a synthetic glucocorticoid currently utilized in the medical fields for the treatment of various types of diseases. The present study aimed to investigate the histological and ultrastructural changes induced in mammalian testis under the effect of hydrocortisone. Twenty adult male rats weighing 150-200g were divided into two groups; group I, injected i.m. with hydrocortisone sodium succinate (30mg/100g b.wt.) , daily for 15 days. Whereas, group II were kept as control. (injected with 0.6ml of bacteriostatic water). Histologically, testes of treated rats displayed thickening of tunica albuginea, disruption of spermatogenesis evident, marked reduction in germ cells caused dilatation of intercellular spaces, detachment of Sertoli cells from the irregular basal lamina, in addition to necrotic Leydig cells with infiltration of the interstitial tissues. Ultrastructurally, treated testes showed thickening and irregularity of the surrounding basal lamina, cytoplasmic vacuolation of atrophied Sertoli cells, shrinkage and pyknotic nuclei of spermatogonia and primary spermatocytes, condensed Golgi apparatus and detachment of the acrosomal granule from the anterior hemisphere of the nucleus of rounded spermatids, and disappearance of elongated spermatids and spermatozoa. Also, necrotic Leydig cells were observed in interstitial tissue. In conclusion, hydrocortisone administration into adult male rats exerts a clear effect on testicular structure and ultrastructure, which leads to much deficiency in their performance. So, it should be utilized under restricted precautions in the medical fields to protect the human health from its hazardous impact.

Key words: glucocorticoids, histology, hydrocortisone, rat, testis, ultrastructure

1. Introduction:

Hydrocortisone is a synthetic glucocorticoid widely administered for the treatment of various types of diseases. It significantly reduced specific physical problems in prostate cancer patients and improved their emotional state (Kornblith *et al.*, 2001), it is used for the treatment of severe liver failure (Harry *et al.*, 2003), acute graft rejection in most forms of organ transplantation, some neoplastic conditions, collagen diseases, dermatological diseases, status asthmatics, allergic and anaphylactic reactions (Rigge and Jones, 2005), mild ulcerative colitis (Schimmer and Parker, 2006), acute pancreatitis (Wang *et al.*, 2007) and as bastion of control the brain swelling before, during, and after neurosurgical procedures, as well as during radiation and chemotherapy in the brain tumor patients (Da Silva and Schiff, 2007).

Jung and Inder (2008) reported that hydrocortisone administration is recommended in a wide scale for patients in the event of stress, severe illness, or surgical procedures; including minor surgery (i.e., hernia repair, laparoscopic cholecystectomy and knee surgery), moderate surgical stress (i.e., open cholecystectomy, partial colon resection, uncomplicated back surgery and hip

replacement), and major surgical stress (i.e., pancreato-duodenectomy, esophagectomy, total colectomy, repair for perforated bowel, cardiopulmonary bypass, ileofemoral bypass and oral surgical stress).

Also, hydrocortisone is the drug of choice for glucocorticoid replacement therapy in adrenal insufficiency diseases (Mah *et al.*, 2004; Salvatori, 2005; Nieman *et al.*, 2006), it is also used in the treatment of congenital adrenal hyperplasia, a group of inherited disorders in which 21-hydroxylase enzyme involved in the biosynthesis of corticosteroids is deficient resulting in low production of cortisol or aldosterone (Schimmer and Parker, 2006) and for the treatment of acute adrenal crisis (Bornstein, 2009).

In 2010, Romer *et al.* elucidated that hydrocortisone has been shown to affect declarative memory. Recently, Wirth *et al.* (2011) declared that intravenous hydrocortisone administration to depressed patients produced mixed effects on mood and emotional processing.

In experimental animals, involvement of hydrocortisone has been studied in some biological aspects on different body organs rather than the testis (Nosenko and Mishunina, 2005; Mantzoros *et al.*,

2006; Tariq *et al.*, 2007; Li *et al.*, 2008; Casella *et al.*, 2010).

These studies indicate that almost no attention has been given for the influence of hydrocortisone administration on mammalian testicular tissues. Therefore, the present study aimed to investigate the effect of hydrocortisone on adult rat testis from the histological and ultrastructural point of view.

2. Materials and Methods:

2.1. Experimental animals

Twenty male Swiss albino rats (*Rattus norvegicus*) weighing 150-200g, acquired from Schistosoma Biological Supply Program (SBSP) Theodor Bilharz Research Institute, were housed in clear plastic cages (2 animals/cage) with wood chips as bedding and given pellet rodent diet, milk and water *ad-libitum*. They were kept under controlled environmental conditions, including a temperature of 25°C and a 12h light/dark cycle.

2.2. Drug used in an experiment.

Hydrocortisone Sodium Succinate available in Egypt under trade name; Solu-Cortef® in the form of 100mg/2ml bacteriostatic water for injection which is manufactured by EGYPTIAN INT. PHARMACEUTICAL INDUSTRIES (E.I.P.I.CO., under Licence of UPJOHN s.a. Puurs-Belgium). It is a highly water-soluble sodium succinate ester of hydrocortisone (Schimmer and Parker, 2006).

2.3. Experimental design

The rats were divided randomly into two even groups; Group I, were intramuscularly injected with hydrocortisone sodium succinate, with a dose equivalent to 30 mg/100g.b.wt. Dissolved in 0.6 ml of bacteriostatic water in a daily manner at 9am for 15 days. This dose was determined in accordance to the dose utilized in previous researches of experimental rats (Bogdanov and Yarushkina, 2004, 2006 & 2007; Yarushkina, 2008). Whereas, Group II (control), were intramuscularly injected only with 0.6 ml of bacteriostatic water in the same manner as group I.

2.4. Histological preparations

The excised testes were fixed in Bouin's fluid for 24 hours, were subjected to the normal procedures for paraffin sectioning, cut at the thickness of 4-6 µm and stained with haematoxylin & eosin stains. The stained sections were examined and photographed by light microscopy (BX-40 Olympus), fitted with 10x - 40x objective lenses with an adjustable numerical aperture (3.3). Images were captured using camera (Panasonic CD-220).

2.5. Ultrastructural preparations

For ultrastructural evaluation by transmission electron microscopy as described previously by Dykstra *et al.* (2002), freshly excised testes were cut into small blocks (1×1mm³), fixed directly in cold 4F1G (i.e. 4% formalin + 1% glutaraldehyde adjusted at pH 2.2) for 24 hours, then were post fixed in 1% osmium tetroxide in 0.1M phosphate buffer (pH 7.3), dehydrated in an ethanolic series culminating in 100% acetone, and infiltrated with epoxide resin. After polymerization overnight at 60°C, semithin sections (0.5 µm) were stained with 1% toluidine blue in 1% sodium borate and examined with light microscope. Areas of seminiferous tubules were selected and the blocks trimmed accordingly. Ultrathin sections (80-90 nm) were cut, mounted on 200 mesh copper grids, and stained with uranyl acetate and lead citrate. The stained grids were examined and photographed by JEOL.JEM-1400-EX-ELECTRON MICROSCOPE at the Central Laboratory of Faculty of Science, Ain Shams University. The photographs were printed on KODABROMIDE F5s GLOSSY Black and White-Schwarzweib- Kodak.

3. Results

3.1. Histological study

Testes of control rats showed normal features of testicular tissue as illustrated in figures (1-3). The testis is enclosed in a thick fibrous capsule, the tunica albuginea. The seminiferous tubules are ensheathed by basal lamina formed of myoid cells. Each tubule possesses epithelial cells involved of Sertoli cells and the germ cells of various stages, covering the complete process of spermatogenesis. Sertoli cells exhibit typical irregular nuclei and well-defined cytoplasm. Spermatogonia are oval in shape, rest upon the basal lamina of the seminiferous tubule. Immediately above them are spherical primary spermatocytes, recognized by their copious cytoplasm and large nuclei containing coarse clumps of chromatin. Secondary spermatocytes are not seen in these sections due to the rapid division processes. Therefore, above the primary spermatocytes, there are large clusters of small rounded spermatids with rounded nuclei devoid of coarse clumps of heterochromatin, followed by elongated spermatids which undergo dramatic shape changes, forming spermatozoa. The interstitium between seminiferous tubules contain distinct Leydig cells and blood vessels.

Sections of testicular tissues obtained from hydrocortisone-treated rats displayed several histopathological changes as illustrated in figures (4-6). The seminiferous tubules surrounded by thickened

tunica albuginea, showing deformed Sertoli cells, being detached from the irregular basal lamina, marked reduction in the germ cells causing dilatation intercellular spaces, spermatogonia manifest vacuolated cytoplasm and pyknotic nuclei, primary spermatocytes reveal pyknotic nuclei, and the rounded spermatids having karyolytic nuclei. The effects are much severe in spermatid differentiation,

Figure (1): Normal testicular tissue architecture of control testis revealing tunica albuginea (TA), seminiferous tubules (ST) ensheathed with basal lamina (BL) and containing spermatozoa (SZ) in their lumens, in addition to the interstitial tissues (IT). (H&E, x330)

whereas there is a complete loss of elongated spermatids and accordingly of spermatozoa, which means that the spermatogenesis was arrested at the stage of rounded spermatids formation under the effect of hydrocortisone treatment.

The interstitial tissues between seminiferous tubules are infiltrated and the Leydig cells have pyknotic nuclei as clearly seen in figure (6).

Figure (2): Normal seminiferous tubule of control testis surrounded by basal lamina (BL) with myoid cells (MC) showing Sertoli cells (SC) and germ cells including; spermatogonia (SG), primary spermatocytes (PS), rounded spermatids (RS) and elongated spermatids (ES). (H&E, x1320)

Figure (3): Normal architecture of interstitial tissue (IT) of control testis embodying clusters of Leydig cells (LC) and blood vessel (BV) and located in between three seminiferous tubules being surrounded by basal lamina (BL) containing myoid cells (MC), having spermatogonia (SG), primary spermatocytes (PS), rounded spermatids (RS) and Sertoli cells (SC). (H&E, x1320)

Figure (4): Destructed testicular tissues of treated testis elucidating thickened tunica albuginea (TA), deformed seminiferous tubules (ST) devoid of spermatozoa and infiltration (If) of the interstitial tissue (IT). (H&E, x330)

Figure (5): Destructed seminiferous tubule of treated testis displaying necrotic spermatogonia (SG) and primary

5 spermatocytes (PS). Detachment of Sertoli cells (SC) from the basement membrane. Dilated intercellular spaces (*) between germ cells are also noticed. (H&E, x1320)

6 Destructed interstitial tissue (IT) of treated testis in between four seminiferous tubules revealing necrotic Leydig cells (LC), vacuolation (V) and infiltrated tissue (If). The seminiferous tubules showing vacuolated spermatogonia (SG), necrotic primary spermatocytes (PS) and rounded spermatids. Beside, deformed Sertoli cells (SC) are clearly seen. (H&E, x1320)

3.2. Ultrastructural study

Ultrastructural examination of control rat testis showed Sertoli cells and germ cells with cellular characteristics typical of those seen in active spermatogenesis. The germ cells in various developmental stages are arranged orderly as illustrate in figure (7). The spermatogonia rest upon the basal lamina of the tubules possessing mitochondria and nuclei with one or two nucleoli, euchromatin and dense clumps of marginated heterochromatin (Fig.7). while, in hydrocortisone-treated rats, the spermatogonia lost their normal architecture, being irregular or pyramidal in shape possessing all the features of necrotic cells as; shrinkage with pyknotic nuclei characterized by chromatin condensation. Accordingly, the intercellular spaces between these necrotic spermatogonia are dilated (Figs. 8 & 9).

The primary spermatocytes of control testis are rounded in configurations with prominent large rounded nuclei having distinct nucleoli, homogenous chromatin materials including both heterochromatin and euchromatin, and surrounded by nuclear membrane. The cytoplasm appear granular, characterized by dispersed oval mitochondria, cisternae of smooth endoplasmic reticulum, lysosomes and Golgi apparatus (Figs. 7 & 10). Whereas, primary spermatocytes of hydrocortisone-treated testis decreased in size, revealing condensed chromatin materials in the nucleus and in the

cytoplasm electron dense mitochondria and vacuoles are seen (Fig. 11).

As shown in figure (12), the electron micrograph of rounded spermatids of control rat testis manifested the formation of the acrosome in developing spermatid. This formation starts with the appearance of a proacrosomal granule in an acrosomal vesicle associated with the Golgi complex, then the acrosomal vesicle enlarged and adhered to the anterior pole of the nucleus, spreading over the hemisphere of the nucleus to form an acrosomal cap. Also, the cytoplasm possesses few stacks of rough endoplasmic reticulum, vacuolated mitochondria and lysosomes. The nucleus is well defined characterized by a single nucleolus, chromatin networks, and surrounded by distinct nuclear membrane. While, hydrocortisone-treated rat revealed rounded spermatids with ruptured plasma membrane in some positions, vacuolated cytoplasm, electron dense mitochondria, condensed Golgi apparatus and acrosomal granule detached from the anterior hemisphere of an obviously atrophied nucleus with disappearance of the nucleolus reflecting stage of karyolysis (Figs. 9&13). As previously mentioned, in the treated rats, the spermatogenesis was arrested at the stage of rounded spermatids formation as revealed by the disappearance of elongated spermatids and spermatozoa in these electron micrographs which means that they were severely affected post hydrocortisone treatment.

In electron micrograph of control testis, Sertoli cells showed distinct nucleus and cytoplasmic characteristics consistent with an active secretory state. It rests on the basal lamina of the tubule, extending towards the lumen of the tubule, filling the narrow spaces between the cells of the spermatogenic series. The cytoplasm contains mitochondria with distinct tubular cristae, cisternae of smooth endoplasmic reticulum, few stacks of rough endoplasmic reticulum, Golgi apparatus and lysosome. The nucleus appears irregular in shape, devoid of heterochromatin, containing a prominent nucleolus, surrounded by nuclear envelop and exhibits deep indentation as clearly observed in figure (14). While, Sertoli cells of hydrocortisone-treated rats are shrunk in size, containing electron dense mitochondria, fragmented smooth endoplasmic reticulum, lysosomes and vacuoles. The nuclei are irregular in shape with deep indentation and containing distinct electron dense nucleoli and prominent electron dense chromatin bodies (Figs 9 & 15). It is clearly noticed in figure (9) that, Sertoli cells detached from the basal lamina and moved towards the lumen of the tubule.

Normal Leydig cells of control rat possess large spherical nuclei with distinct nucleoli, euchromatin and coarse clumps of peripheral heterochromatin, in addition to the cytoplasm containing cisternae of smooth endoplasmic reticulum, mitochondria and lipid droplets. Monocytes are also found in the interstitial tissue. This cell is the largest white blood cells, highly motile, phagocytic cell and is the precursor of macrophages. It is characterized by a large eccentrically placed bilobed nucleus. Numerous small pseudopodia extend from the monocyte for its phagocytic role and amoeboid movement (Fig. 16).

Examination of the interstitial tissue from hydrocortisone-treated testis showed necrotic Leydig cells having deformed mitochondria, reduced smooth endoplasmic reticulum and few lipid droplets. Blood capillary lined with endothelial cells is also seen (Fig. 17).

4. Discussion

The testis is considered to be the most important organ in the male reproductive system. It is characterized by two main functions, synthesis of steroid hormones and production of spermatozoa (Carreau *et al.*, 2002). Various factors could affect spermatogenesis, among these factors are chemical agents, such as medicines and toxic elements in environmental pollution (Yano and Dolder, 2002).

Several studies had been carried out to investigate the severity of adverse effects of hydrocortisone as a synthetic glucocorticoid drug on

different body organs such as the pancreas (Gloor *et al.*, 2001), reproductive aspects of female rats (Piffer and Pereira, 2004), the thymus (Rodrigues-Mascarenhas *et al.*, 2006), the liver (Gevorgyan *et al.*, 2008), the hypothalamo-hypophyseal-adrenocortical system (Yarushkina, 2008) and the hippocampus (Tata and Anderson, 2010). Unfortunately, no literatures can be detected on the impacts of hydrocortisone on the structures and ultrastructures of mammalian testis. So, the present work aimed to throw the light on such studies in adult albino rat testis.

The results of the present study revealed various histological and ultrastructural alterations of the testicular tissues. The surrounding basal lamina of the tubules was thickened with irregular wavy appearance. The basal lamina plays an important role in maintaining substance transportation between interstitial tissue and spermatogenic epithelium and in maintaining the structural and functional integrity of tissues (Richardson *et al.*, 1998).

Figure (7): Seminiferous tubule of control rat surrounding by thin basal lamina (BL) and formed of; spermatogonia (SG) possessing rounded to oval nuclei containing nucleoli (Nu), euchromatin (Eu) and margined heterochromatin (Ht). The cytoplasm containing mitochondria (M), and primary spermatocytes (PS) which are rounded in shape having large rounded nucleus (N) containing; nucleoli (Nu), heterochromatin (Ht) and euchromatin (Eu). Mitochondria (M), smooth endoplasmic reticulum (SER) and lysosomes (Ly) are seen clearly in the cytoplasm. (x4000).

Figure (8): Seminiferous tubule of hydrocortisone-treated rat displaying degenerated spermatogonia (SG) with irregular shapes, detached from the thickened basal lamina (BL) and having pyknotic nuclei (N) with condensed chromatin, in addition to increased intercellular spaces (*) between them. (x4000)

Figure (9): Another tubule of treated rat surrounded by an irregular, thickened basal lamina (BL) and having degenerated spermatogonia (SG) with trapezoidal shape and increased intercellular spaces (*) between them, round spermatids (RS) with detached acrosomal cap (AC) of their nuclei, in addition to Sertoli cell (SC) detached from the basal lamina, resting in front of the spermatogonia with destructed cytoplasm having few mitochondria (M). Besides, Leydig cell (LC) with pyknotic nucleus is also noticed. (x4000)

Figure (10): Primary spermatocyte of control testis having large rounded nucleus (N) containing nucleolus (Nu), heterochromatin (Ht) and euchromatin (Eu) and surrounded by nuclear membrane (Nm). The cytoplasm containing oval mitochondria (M), smooth endoplasmic reticulum (SER) and Golgi apparatus (GA). (x6000)

Figure (11): Primary spermatocyte of hydrocortisone-treated testis showing an atrophy in size, pyknotic nucleus (N) having condensed chromatin materials and the surrounding cytoplasm containing deformed mitochondria and vacuoles (V). (x6000)

Figure (12): Rounded spermatid of control testis illustrating the formation of the acrosome, indicated by the presence of a proacrosomal granule (AG), acrosomal cap (AC), Golgi apparatus (GA) over the anterior hemisphere of the nucleus (N) which is rounded in shape, containing distinct nucleolus (Nu), homogenous chromatin materials and surrounded by nuclear membrane (Nm). The cytoplasm containing vacuolated mitochondria (M), few stacks of rough endoplasmic reticulum (RER) and lysosome (Ly). (x10,000)

Figure (13): Rounded spermatid of hydrocortisone-treated testis exhibiting ruptured plasma membrane (arrows), detached acrosomal granule (AG) from the nucleus (N), condensed Golgi apparatus (GA), destructed stacks of rough endoplasmic reticulum (RER), mitochondria (M) in which some of them revealed deep electron density and numerous vacuoles (V). The nucleus showing an obvious atrophy in size with disappearance of the nucleolus reflecting stage of karyolysis. (x10,000)

Figure (14): Sertoli cell of control testis revealing irregularly shaped nucleus (N), devoid of heterochromatin, containing one prominent nucleolus (Nu), and enclosed with nuclear envelope that exhibiting a deep indentation (arrow). The cytoplasm containing mitochondria with distinct tubular cristae (M), cisternae of smooth endoplasmic reticulum (SER), few stacks of rough endoplasmic reticulum (RER), Golgi apparatus (GA) and lysosomes (Ly). Part of the basal lamina (BL), with myoid cell (MC) are seen. (x7500)

Figure (15): Sertoli cell of hydrocortisone-treated testis having cytoplasm containing electron dense mitochondria (M), lysosome (Ly), fragmented smooth endoplasmic reticulum (SER) and vacuoles (V). The nucleus (N) lacking of nucleolus, but containing two dense chromatin bodies (CB) adjacent to its inner nuclear membrane which is characterized by the presence of two deep indentations (arrows). Part of irregular, thickened basal lamina (BL) is also clearly observed. (x7500)

Figure (16): Interstitial tissue of control testis revealing normal fine structure of Leydig cells (LC), characterized by cytoplasm contain mitochondria (M), smooth endoplasmic reticulum (SER) and lipid droplets (Li), in addition to oval to rounded nuclei (N) containing one or two nucleoli (Nu), heterochromatin (Ht) and euchromatin (Eu). A monocyte cell (Mo) is also noticed with its eccentric nucleus (N) and numerous small pseudopodia (P) extending from it. (x4000)

Figure (17): Interstitial tissue of hydrocortisone-treated testis displaying atrophied Leydig cells (LC) cytoplasm containing electron dense mitochondria (M), few lipid droplets (Li) and the nuclei (N) are irregular in shape showing signs of pyknosis. Blood capillary (Cap) lined by endothelial cell (EC) is also noticed. (x4000)

Many testicular disorders are associated with a thickened aspect of the tubular wall of the seminiferous tubules, which impairs the relationship between the inner tubular population and the interstitium. During the pathological thickening processes, Sertoli cell functions are progressively altered and eventually suppressed. According to the disturbance progresses, the germ cells display a progressive arrest of the spermatogenic processes. Subsequently, the lamina propria begins to separate, then thicken and finally shrunk. At the end of this process the basal lamina is absorbed, and leaves the so-called ghost tubules in the tissue (Anniballo *et al.*, 2000). Altered basement membrane structure has been associated with severe functional impairment of the testis. This destruction might subsequently affect transportation of oxygen, hormone, nutrition, and metabolites (Zheng *et al.*, 2008).

Interactions between Sertoli cells, peritubular myoid cells, Leydig cells, and germ cells are thought to be essential for spermatogenesis. Each of these interactions must be communicated through the extracellular matrix of the basement membrane. Many reports have demonstrated that over expression of the subtypes of type IV collagen correlates with abnormal thickened basement membrane and it is related to spermatogenic dysfunction in human and other mammals, since type IV collagen is a major constituent of mammalian basement membrane and is secreted by myoid cells and Sertoli cells (Dobashi *et al.*, 2003; Mattias *et al.*, 2005).

Sertoli cells have been shown to be the target for various toxicants (Krishnamoorthy *et al.*, 2005). In the present work, damage of Sertoli cells was evident following hydrocortisone administration. Dilated intercellular spaces and loss of contact between germ cells is apparently due to Sertoli cell disturbances which also lead to loss of these germ cells and finally to the destruction of testicular tissue and infertility (Monsees *et al.*, 2002). Sertoli cells foster the development and maintain the viability of germ cells by secreting hormonal and nutritive factors into a specialized compartment (blood-testis barrier), formed by tight junctions between the adjacent Sertoli cells and the germ cells. Also, it forms the sites of attachment of germ cells and provide physical support to them (Richburg, 2000; Sawada and Esaki, 2003). During spermatogenesis, spermatogonia differentiate into spermatocytes that cross through the blood-testis barrier as they mature and traverse the tubular lumen (Cook and Saunders, 2002; Siu and Cheng, 2004).

Spermatogonia demonstrated severe defects post hydrocortisone administration, they lost their

normal shapes, possessing features of necrotic cells. As De Rooij and Russell (2000) described, spermatogonia are particularly vulnerable to toxicants and physical agents. In particular, because of their mitotic activity, they are more vulnerable than Sertoli, Leydig cells and spermatids. Spermatogonia have three major roles; first, spermatogenesis is initiated via spermatogonia. Second, the population of germ cells is greatly increased via the mitotic activity of spermatogonia, as one spermatogonium on average goes through 8 to 9 divisions before differentiating into a spermatocytes. Third, regulation of germ cell numbers is accomplished in the spermatogonial population of cells. Thus, alterations of spermatogonia will be reflected on the development of the following stages of spermatogenesis.

Different defects in spermatocytes and spermatids post hydrocortisone treatment may reflect the disturbances in the microenvironment of the Sertoli cells, that affect the protein synthesis machinery essential for germ cell differentiation. Proteins necessary for the differentiation of germ cells are secreted at their highest rates in the testis during spermatid elongation and spermiation (Manivannan *et al.*, 2009).

The present results showed that hydrocortisone treatment also exerts an effect on Leydig cells; showing remarkable decrease in number and size. Close relationship between Leydig cells and blood vessels suggests that these cells are at high risk of exogenous toxicants. In normal testicular function, Leydig cells are the centers of fertility regulation and reproductive health (Boekelheide, 1993). Within the testis, steroidogenesis occurs in the Leydig cells. Inside these cells, the steroidogenic pathway begins in the cytoplasm and includes chemical reactions that occur in the mitochondria and smooth endoplasmic reticulum, where the final end product –testosterone- is produced (Dharia *et al.*, 2004).

The results of the present study are in accordance with other previous studies using other drugs, such as those reported by Yano and Dolder, (2002) after paracetamol treatment into rats, after injection of rats with Nandrolone decanote -an anabolic androgenic steroid drug- (Mesbah *et al.*, 2008), and post long-term treatment with the methanol subfraction of *Carica papaya* seeds in rats (Manivannan *et al.*, 2009).

In conclusion, data from the present study showed that hydrocortisone administration into adult male rats exerts a clear effect on testicular structures and ultrastructures including degenerated changes of germ cells, Sertoli cells, and Leydig cells. These changes reflect on their functions exerting deficiency in their performance. So, it should be utilized under

restricted precautions in the medical fields to protect the human health from its hazardous impact.

Abstract: One of the most important subjects in management research is empowerment of employees. Many researchers have studied empowerment in different organizations, and presented different theories about it. In this paper in order to find relationship between management system and increasing employee's empowerment, one main and three sub-hypotheses have been posed: Main hypotheses: the existence of integrative management systems would effect on increasing the employ's empowerment system ISO14001 and occupational health management system ISO18001. The method of research is experimental and tools to gather the data is questionnaire. The statistical society of this research is the employees of Shazand Power Generation Management Co. the number of sample is that had responded to the questionnaire were 100 employees. After analysis the data by software SPSS the following results had been seen: The existence of management systems with 0.802 coefficient correlation would effectively and strongly impact the employ's empowerment increasing and also the result of this study indicated that the existence of environmental management system with 0.633 coefficient correlation, the existence of quality management system with 0.733 coefficient correlation and the existence of occupational health and Safety management system with 0.833 coefficient correlation have had the most effect on the employees' empowerment. [Mojtaba Rafiey, Hadi Ghaffari, Mahdi Bandarkhany. Review of the effectiveness of management systems on empowerment of employees: A case study in an Iranian Power Generation Management. Journal of American Science 2011;7(6):1204-1210]. (ISSN: 1545-1003). <http://www.americanscience.org>.

Key words: Integrative management system, Quality management system ISO9001, Environment management system ISO14001. Empowerment

1. Introduction:

Quality and quest for quality, along, along with achieving an acceptable and promoting business process from various viewpoints, has been one of the most important. Debates during the past few years. Progress in the field of business and a bigger share of market along with access to such issues as customer's satisfaction, meeting legal and international requirements and are amongst the most fundamental factors persuading institutions to move towards systematizing their activities. Meanwhile, various international standards in the fields of quality, environment, safety and professional health, have had a fundamental and undeniable role. Similarities of such management systems and advantages of their synchronous implementation, has raised the issue of integrated management systems. Therefore the objective of establishing the integrated management systems and executing the empowerment process is to improve the quality level of products and speed of providing services the result of which being, satisfaction of expectations, demands, satisfaction of transformer, more profit and increased market share.

2. Problem statement and its importance:

The fact is that during the recent years, in line with evolution of the concept of quality and producing

superior products, other issues have been raised on behalf of state and social organizations such as the environment protection organization, insurance and social security institutions and ... without regarding which, the possibility to keep market, and survival in the competition field will not be easily feasible. On one hand, regarding the ever increasing growth of population and limitation of natural resources, environmental protection as one of the most crucial problems of the human society has been raised and this topic is not limited to the political and geographical border and demand for collective endeavor on behalf of all the inhabitant, of the earth globe. In the issue of unstained development too, optimal exploitation of natural resources, especially non renewable resources, quality products production and increased productivity has a crucial importance. Therefore, producing better product should not be done at the expense of damaging environment and destroying the human. Based on the above said reasons, many firms, in addition to obtaining the Quality Management system certificate (QMSC)², fake actions to obtain the Environmental Management Systems (EMS) and the Occupation Health and Safety Management System (OHSMS) and obtaining the relevant certificates from the certificate granting firms. Regarding the importance of establishing the

integrated management system in the institutions and empowerment of staff, in this research attempt has been made to answer to the following questions:

1. Is the integrated management system effective on empowerment of employees?
2. Which of the standard systems is more effective on empowerment of employees?

3. The research objectives

The main objective of the present research is to review effectiveness of executing the integrated management systems in the shazand power generation management Co. and identify the effective and key factors on increasing effectiveness of the management systems so that the power station directors can, through activating these factors achieving the objectives defined in the mission and policy of the institution.

Also, regarding that the present research is an applied one, several applications can be expected of it inducing:

1. Finding the relation between the standards and the manpower.
2. Is establishment of the management systems effective on empowering staff and how and to which degree?
3. Level of satisfaction of employees of establishment of such systems and the procedure of dealing with such cases.
4. theoretical bases of research:

A: The integrated management systems:
To do any type of business, there is need for a criterion for evaluating the activities and standards have been able to do this job. To establish an effective system in the institution, the four stages of planning, doing (execution), checking and action should be performed. The expanse of application of management standards depend on such factors as policy of the institution and nature of the activity conditions. The main factor has been the concept of integrating the triad interaction systems of management between them. The amplifying factor of the concept of integrating the management system enjoys many advantages arising from their implementation for the institutions [1].

The integrated management systems means a mixture of several management systems established, executed, monitored and measured as a limit and administered as a process.

The integrated management system includes the Quality Management System, Environmental Management System, and the Occupational Health and Safety Management Systems based on the interactional ISO, ISO 9001:2008, 14001:2004 and OHSAS 18001:2007 standards [2].

Synchronous establishment of the three systems will assist a combined or assembled management system. In this system, requirements and demands of the management, quality, and safety and environment systems are combined and obey a unique documentation system. In this system, the volume of the previous documents of quality is decreased and through integration into the safety management system is significantly reduced and a unique system is codified for all the free systems. Also the executive methods and directions are adapted to requirement of all the three systems and the volume of documents is reduced up to a one third. In the policy of these three systems, the main objectives of quality, environment and safety are defined. In the other words, at this stage the institution will be able to adapt its system with the integrated management system.

Advantages of the integrated management systems: some of the advantages of the integrated management system are as follows:

- Definition of the objective in a clear form and regarding the institution's policy.
- Preventing traveling the wrong courses towards the objective.
- Removing the interference and disharmony of the various intersystem mechanisms.
- Reduction of costs due to duplications.
- Establishment and expansion of the dynamic data circulation in the system.
- Providing the possibility of reviewing the system and removing the defects and weak points of the system.
- Provision of the possibility of obtaining feedback from details of the activities.
- Provision of a background for the various process predictions. [2].

4- Definition of empowerment

The English word 'empower' in the Oxford concise dictionary has been defined as to become powerful, authority to act making powerful and granting permit. This term includes the power and freedom of action for enforcing one's will and in the institutional concept; it means the change of culture and courage for establishment and running an organizational environment.

- Empowerment is a process through which a manager helps employees to obtain the ability required for independent decision taking. This process is effective not only on performance but also on personality of individuals [3].
- Empowerment means development of the individual's potentials and competence for attaining continuous empowerment in the institution's performance.

- Promotion of the employees' ability in better use of their power of change and analysis, having in sight in performing their works and complete participation in decisions effective on their lives.
- Empowerment is the process of developing the institution, leads to increase power of the staff to solve problems, promotion of their political and social insight and makes them able to recognize and control the environmental factors.
- Empowerment provides an environment in which employees can work with more authority and have a role in the process of change and product improvement, reduce their needs to their immediate supervisor and take part in realizing the firm's objectives [4].
- Empowerment is the process of achieving continuous empowerment in the institution's performance through developing influence based on competence of individuals and group in all areas and duties which are effective on performance and general operation of the institution [5].

5 - The fox empowerment model

Fox believes that empowerment is a process through which the empowerment and competence is developed information is shared and resources and support is also provided. Fox is attempting to provide a model for empowering the employees.

In this model each of the empowerment components (culture, contribution in information, development of competence, provision of resources and support) are singly tested and finally a model has been provided based on ethical requirements to comprehend and employ empowerment of employees. [3].

Fox in his proposed model believes that so far the employees have not developed their knowledge and skills during traineeship and while performing a duty they should be regarded as an apprentice and then, when they promoted their knowledge and skill, can continue their work as a specialist worker and finally become a master in their field of activity.

Organizational culture

Harrison and Stocks have raised an interesting debate on the method in which the culture of an organization can lead to empowerment. These two, consider the organizational culture that part of the institution which gives one a special feeling, Harrison and stocks believe that the ratio of culture to institution is similar to the ration of personality to an individual which is apart from beliefs, values, work styles, and relations which distinguishes an institution from another [20].

Data distribution

Data distribution amongst employees can inform employees of problems and events, and change them to powerful individuals. Once this situation is provided, little by little work will precede through another procedure. Task structures from proportional to needs and specialties (not through the order of hierarchical reports). Once this happens, and data is available extensively and in a short period, the institution can no more remain as it is [3].

Empowerment won't be possible but through commitment of managers to education and exchange of information with the employees to whom they paid no attention (Brandt, 1998:247).

Competence Enhancement

Another of the empowerment requirements is nurturing competences of individuals and groups in the organization. No doubt all individuals have potentials in themselves to empower of which, such competences should be nurtured and developed. Individuals require nurturing competences needed for legal participation. Management and staff both have an identical Responsibility to nurture such competences. Individuals and groups should attempt to nurture in themselves the needed knowledge for informed and constructive participation. Management in turn should provide the support needed by employees everywhere so that they can nurture the debated participation skill in themselves. Some of the pivotal competences are:

- self management ability
- Critical though
- Communication establishing skills
- Flexible decision taking

Access to sources

In addition to data provision, power is enhanced via providing other sources which assist individuals to perform their duties. In this case, managers empowered by others, are mostly like defenders of a football game other than players of the attack line they are. Mostly resource suppliers and obstacle removers rather than directors and commanders. [6].

Support

The technique or approach of assisting other to experience empowerment, is to provide social and emotional support for them. In the event that it is intended that employees feel empowerment, manager should praise them, persuade them, support them and ensure them. [3].

Challenge towards empowering employees

The most crucial existing challenges can be reviewed from the two managerial and consequential dimensions.

A. Managerial Challenges

- * Lack of self-concept
- * Managerial security threat [7]

Achievements of the empowerment programs

Empowerment programs provide the institution with the possibility to behave in a creative and innovative way and present it business schemes in such a way which can retain always its status in the best possible situation. The most conspicuous advantage of employing such schemes is that it provides the motives for ever increasing understanding and commitment of staff and the institution.

Here we will point out to some of the other most important executive benefits of the power enhancing programs:

- * Concentration on customer- orientation and attaining satisfaction of the referring customers as the main axis of the crucial institutional decisions.
- * Taking crucial organizational decisions in a team and group form.
- * Participation and sharing employees in responsibilities, skills and organizational authorities.
- * Control and evaluation of individual and organizational performance by the evaluating groups.
- * Establishment of agility in the institution and rapid accommodation with environmental changes and modifications.
- * Dominance of the key skill of working in community and with others as the basic organizational thought.
- * Changing the concept of commanding to the ability to influence on others.
- * Changed responsibility of managers from mere control to releasing hidden abilities of staff [8].

6. Research Method:

Regarding importance of subject in this research, various dimensions of the managerial and empowerment model of the Fox correlation research procedure has been used. In this research, the statistical population includes all employees of the Shazand Power Generation Co. (480 individuals). In the present study the simple random method was employed and the sample volume according to the John Haravy statistical formula was specified to be 92. For more reliability of results, 100 questionnaires was distributed amongst members of the statistical population. Local territory of this research is the Shazand Thermal Power Station.

To collect required data library and internet search tools and various papers were used.

In this research, empowerment of employees was used as dependent variable and the integrated management systems as independent variables.

For this purpose, a questionnaire with 45 questions was designed in the following two sections:

A. Factors of the integrated management systems, a total of 25 questions including: The occupational health and safety management systems (9 questions),

the factor of environmental management system (7 questions) the quality management systems (4 questions).

B. Powerful factor, a total of 20 question including the organizational culture (4 questions) participation in data (data sharing) (5 questions), competence development (4 questions).

Also in this research, for the purpose of questionnaire assessment the Cronbach alpha test was used and in a volume samples of 30 individuals the Cronbach alpha of 0.843 was obtained indicating that the validity and stability of the system is appropriate. Since the research findings is base on polling from the respondents, based on Likret scale therefore to analyze the obtained results the inference spearman correlation was used as follows:

$$R_{rth_0} = 1 - \frac{6\sum D^2}{N(N^2 - 1)}$$

Also for grading the integrated management systems, the standards were separately graded according to the Freedman test.

7. Findings of the research

In conclusions where tests are used in which the relation between two variables are surveyed, if the correlation coefficient between the two variables is less than 0.3, the relation between the two variables is evaluated as being weak and in the event of this coefficient's sum being between 0.3 and 0.7, this relation would be medium and in case of its sum exceeding 0.7 it means that there is a powerful relation between the two variables. Obtained results are presented in the following table:

Empowerment of employees	Factor of the management systems	Correlation Coefficient
	The quality Management System	0.733
	The Environment Management System	0.633
	The Occupational Health and Safety Management System	0.866

As it can be seen in the above table, the highest correlation exists between the occupational health safety of employees and empowerment (0.866) and the least correlation exists between the environment management system and empowerment of employees (0.633).

A. Conclusion from the first secondary hypothesis

Statistical hypotheses regarding the first research hypothesis was codified and tested as follows:

∩ There is no significant relation between establishment of the quality management standard system and empowerment of employees:

H_0

There is a significant relation between establishment of the quality management standard system and empowerment of employees: H_1
Following performing the pertinent test the P-Value = 0.000 was obtained therefore the H_0 hypothesis was rejected and the H_1 hypothesis was accepted. The correlation coefficient between the two factors of the quality management system and empowerment of (0.733) was obtained. As a result, it can be stated that establishment of the quality management system had a positive effect on empowering employees at the Shazand Power Generation Co. Management.

B. Conclusion regarding test of the second secondary hypothesis:

The statistical hypothesis regarding the second secondary hypothesis was codified as follows:

There is no significant relation between establishment of the standard of environment management and empowerment of employees: H_0

There is significant relation between establishment of the environmental management standard and empowerment of employees:

H_1

Through performing the relevant test, the p-value= 0.000 is obtained. Therefore the hypothesis H_0 was rejected and the hypothesis H_1 was accepted. Since the correlation coefficient of (0.633) was obtained between the environmental management standard and empowerment of employees, it can be concluded that establishment of the above said system also has a medium effect on empowerment of employees in the Shazand Power Generation Management Co.

C. Conclusion regarding the third secondary hypothesis tests

The statistical hypothesis regarding the third hypothesis was also codified as follows:

There is no significant relation between establishment of the occupational health and safety management system and empowerment of employees: H_0 there is a significant relation between establishment of the occupational health and safety management standard and empowerment of employees: H_1 .

Through performing the relevant test, the p-value = 0.000 was obtained, therefore the H_0 hypothesis was rejected and the H_1 hypothesis was accepted. Thence the correlation coefficient between the occupational health and safety management system standard and empowerment of employees (0.866) was obtained thus it can be concluded that establishment of the above said system as well has a significant effect on empowerment of employees in the Shazand Power generation Management Co.

D. Conclusion concerning the main hypothesis of research:

In this research, the integrated management systems were segregated into three systems of quality management, environmental management and health and safety management and defined based on the Fox model for empowerment of employees and its factors along with identification of IMS systems and presented based on constitution of the Shazand Power Generation Management Co. Statistical hypothesis regarding the main hypothesis of the research were codified as follows:

There is no significant relation ship between establishment of the management systems and empowerment of employees: H_0

There exists a significant relationship between establishment of the management systems and empowerment of employees: H_1 .

Through performance of the test, the P-value = 0.000 was obtained. Thus the H_0 hypothesis was rejected and the H_1 hypothesis was accepted.

Therefore in this research through test effectiveness level of the management systems on empowerment of the Shazand Power Generation Management Co. was studied and it was revealed that the correlation coefficient between the integrated management systems (IMS) and empowerment of employees is 0.802 indicating that there is powerful and effective relationship between these two parameters.

Conclusion

If we look at the management of the Shazand Power Generation Co. it will be revealed that the two principles of empowering employees and performing all commitments of the integrated management are the ideals, mission and organizational delegation of the Shazand Power Generation Management Co. Therefore, co-direction and relationship between these two parameters was considered. Obtained results indicated that establishment of management systems has a significant and powerful relationship with empowerment of employees.

In the first hypothesis, it was attempted to assess the effect of establishing the quality management system on empowerment of employees. Therefore regarding the definitions provided of the above said system and empowerment of employees, "empowerment is the process of achieving continuous improvement in performance of the institution through development of extended influence based on competence of individuals and groups in all areas and for all duties influencing their operation and general performance of the institution" [5]. Also, apart from the extensive application that empowerment has obtained in various social, political and educational areas, this idea has found a fundamental position in present

movements of institutions towards quality management and continued improvement.

Regarding the fact that manufactured product of the Shazand Power Generation Management Co., is required by the national power network however, uniform product production and its not being seen by the employees has caused this factor of quality management system to have a moderate effect on empowerment of employees. On the other hand however, since performing commands and standard points of quality management is obligatory, employees deem themselves committed to perform it to prevent unwanted problems and trips in power generation. Also, regarding the result obtained in test of the second hypothesis, it can be concluded that establishment of the environmental management system as well will have a moderate effect on empowerment of employees in the Shazand Power Generation Co. Therefore, since execution of command and environmental points is directly entrusted with the authorities of the power station and codification of schemes to prevent air pollution is continued by the Environment Department experts and experts of the Bakhtar Regional Power and the Tavanir Co. as well from which the employees are informed at on moderate level and only a few of them are involved in these issues however execution of schemes of waste reduction and developing the culture of reducing pollution, are included in the programs of the Bureau of Education and Management systems from which the employees have goods education and sufficient information.

In the third hypothesis test, regarding the high coefficient obtained, it is revealed that establishment of the above said system has also a very high effect on empowering of employees at the Shazand Power Generation Management Co. This is because from the very beginning of formation of the Shazand Power Generation Management Co. extensive activities were done regarding promotion of the safely culture at the employees level examples of which are as follows:

1. Employment of the visual management technique for the safety principles and criteria: in this method, the safety signal relevant to business in a beautiful and desirable form was installed in all departments such that such signals were seen in all spaces and passage locations of employees.

2. All the employees received continuous safety education such that it could be claimed that the highest contribution of education concerned the safety issues and that this training was provided at a very high and quite technical level with the technical staff however for the administrative staff it was also provided.

3. Commitment of all managers and staff to safety criteria is another of the crucial factors effective on increase correlation intensity. From the establishment of the Shazand Power Generation Management Co.

This commitment has been established and continued to present. Implementation of the occupational health and safety management and intermixture of the safety issues with routine affairs of staff was also another factor effective on increased correlation intensity.

Finally regarding the general results obtained in this research, it was revealed that there is a powerful and effective relationship between the integrated management systems (IMS) and empowerment of the employees at the Shazand Power Generation Management Co. therefore it is recommended that, due to importance of occupational and safety of employees and observing the environmental issues and observance of quality standards and as a whole execution of the integrated management systems, this research be implemented in a comparative form in all the state and private sectors in the power industry plants.

The Potential Health Hazard of Tartrazine and Levels of Hyperactivity, Anxiety-Like Symptoms, Depression and Anti-social behaviour in Rats

Mervat M. Kamel*, Heba S. El-Iethy

Department of Animal Hygiene and Management, Faculty of veterinary Medicine, Cairo University, Cairo, Egypt

*mevy58@yahoo.com

Abstract: The current research aimed to determine the influence of different doses of exposure to tartrazine on levels of hyperactivity, anxiety, depression and anti-social behaviours in rats. Forty five weanling male Wistar rats were randomly assigned into 3 groups of 15, divided on 2 replicates and administered our treatment daily in drinking water at different concentrations; 0, 1% and 2.5% for a 16 weeks period. Different animal models of anxiety; open field, elevated plus maze and dark-light transition tests were employed in our study. Tests for depression as well as social interaction were also used. Tartrazine-treated rats showed hyperactivity in open field test presented by increased horizontal locomotion. Anxiogenic effect of tartrazine was evidently observed during open field, elevated plus-maze and dark-light transition tests. Furthermore, tartrazine intake significantly promoted depression as expressed by prolonged immobilization during forced swim test. Impairment in social interaction test was also detected signifying the relevance of administered dose especially on numbers of bouts of social contacts. This study provides sufficient scientific evidence that a causal link truly exists between tartrazine and inflection of hyperactivity, anxiety and depression-like behaviours in rats and points to the hazardous impact of tartrazine on public health.

[Mervat M. Kamel, Heba S. El-Iethy. The Potential Health Hazard of Tartrazine and Levels of Hyperactivity, Anxiety-Like Symptoms, Depression and Anti-social behaviour in Rats. Journal of American Science 2011;7(6):1211-1218].(ISSN: 1545-1003). <http://www.americanscience.org>.

Key words: Food azo-colours tartrazine, hyperactivity, anxiety, depression, social interaction, Wistar rats.

1. Introduction:

Color additives are used in a wide variety of foods such as beverages, dairy products, cereals, bakery goods, snack foods and ice creams. Although there are strict guidelines for chemicals to be approved as food additives, the safety of food colorants has not been rigorously proven, and acceptable daily intake (ADI) has been used to minimize any possible unfavorable effect of the dyes. Food azo-colours tartrazine is one of the most widely used artificial foods, drugs and cosmetic dyes.

Several human studies have related artificial food colorants such as tartrazine, sunset yellow, carmoisine and ponceau with conduct disorders (Weiss et al., 1980; Schab and Trinh, 2004). Moreover, increasing evidence suggests the potential toxicological risk of tartrazine (Mehedi et al., 2009). In addition, Schauss (1984) and Bateman et al. (2004) concluded general adverse behavioural and psychological effects with artificial food colorants in children.

A number of data has described tartrazine-related hyperactivity in children (Schab and Trinh, 2004; McCann et al., 2007). Moreover, noticeable effect of tartrazine on the behavior of young mice has been reported (Tanaka, 2006; Tanaka et al; 2008). Although several researches have linked tartrazine ingestion to a variety of immunologic responses

including anxiety and clinical depression (Rowe and Rowe, 1994), little rigorous research in the field of toxicological effects of tartrazine on behaviours relevant for models of CNS disorders, such as anxiety, depression and social behaviour were verified until recently.

Therefore, the goal of this study was to explore the adverse effect of long term exposure to food colorant tartrazine on hyperactivity as well as mood-like behaviours in the form of anxiety, depression and social interaction in rats.

2. Materials and Methods:

2.1. Animals and housing:

Forty five weanling male Wistar rats, weighing approximately 40-50 g were used in this experiment. Animals were obtained from the Unit for Laboratory Animals at Faculty of Veterinary Medicine, Cairo University. They were maintained in plastic cages, with stainless steel wire lids (bedded with wood shavings), on a standard laboratory feed diet. Feed and water were offered ad libitum. Rats were housed at a controlled temperature of $21 \pm 1^\circ\text{C}$, 60 % humidity and under a 12-h-light:12-h-dark schedule. All efforts were made to minimize the numbers of animals and their suffering in this study through following the guidelines released by Cairo University Policy on Animal Care and Use.

2.2. Administration of tartrazine:

Tartrazine (FD and C Yellow No. 5) was obtained from Sigma chemical Company (Sigma, Aldrich, USA) and dissolved in tap drinking water at a different concentrations; namely 0%, 1% (low dose) and 2.5% (high dose) (Mehedi et al., 2009). Rats were randomly divided into three groups of 15 animals, each and provided ad libitum access to drinking water containing tartrazine for 16 weeks. The control group received tap water only.

2.3. Behavioural measurements:

Behavioural tests were performed in the first half of light phase of the light/dark cycle. All behaviours were scored by a single trained observer unfamiliar with treated animals. Hand operated counters and stop watches were used to score animals' behaviour. Behavioural tests were separated by at least 24 h from each other and executed in the same order presented below.

2.3.1. Open field behaviour test:

The open field test provides simultaneous measures of locomotion, and anxiety (Kelly, 1993; Millan, 2003). The open field used was a square wooden arena measured (90 x 90 x 25cm). The wood of the apparatus is covered with a plastic laminate (formica), which prevents absorption of fluids (urine of rats). The floor was divided by black lines into 36 small squares (15 x 15cm). The open field maze was cleaned between each rat using 70% ethyl alcohol to avoid odor cues. The rats were carried to the test room in their home cages and tested once at a time for 5 minutes each. Rats were handled by the base of their tails at all times. Rats were taken from their home cages and placed randomly into one of the four corners of the open field facing the centre. The behavioural scores measured in this experiment included total numbers of line crossings, rearing against the wall, grooming, stretch attending posture and fecal boli.

2.3.2. Elevated plus maze test:

The elevated plus-maze was used for testing of anxiety and emotionality. The degree of avoidance of the open arms of the maze has been considered as a measure of strength of fear drive (Trullas and Skolnick, 1993). The apparatus consists of 4 crossed arms, two open arms (50 x 10 x 30 cm) and two closed arms (50 x 10 x 30 cm). The maze was elevated 65 cm above the floor. The rat was placed in the centre of the maze and the number of entries in open and closed arms, respectively, as well as the time the animal spent in the open and enclosed arms during a period of 5 min test session was recorded (Kierstin, 2003; Walf and Frye, 2007). After each

trial the maze was wiped out with a cloth dipped in 70% ethyl alcohol and allowed to dry.

2.3.3. Light-Dark transition task:

The light-dark box apparatus consisted of a light, open topped, opaque, plexiglas box connected to a dark, closed topped, plexiglas box, each compartment measuring (30 x 40 x 40 cm). The boxes were connected by a small opening that allows the rat to cross between chambers. The rat was placed in the light box, allowed to move freely between the chambers, and its location was recorded for 5 min. The time spent on the light side of this apparatus during the 5 min test session compared to the dark side was recorded and used as an index for anti-anxiety behavior (Hascoet et al., 2001; Walf and Frye, 2005). Light box entry was defined as the rat having all four paws into the light box.

2.3.4. Forced swim test:

Rats were tested in the forced swim test as previously described by Frye and Walf (2002). Rats were placed in cylindrical container (50 x 20 cm) filled with 30 cm of 22°C water. The water level does not allow the rat to rest on its tail, or escape the cylinder by climbing out. The rat was placed in the water for 6 min. The time spent floating (represented immobility) was scored during the last 3 min. The time spent immobile is considered as an index of depression-like behavior in rodents (Sanchez and Meier, 1997).

2.3.5. Social interaction test:

On the day of the experiment, animals were socially isolated in plastic cages measuring (43 x 28 x 15 cm) for 3.5 h prior to the experiment. The task was conducted by placing two animals belonging to the same experimental group, but from different cages, into the test cage for a 15-min period. Tested pairs did not differ in body weight by more than 15 g. The social behaviour was assessed for a pair of animals (Schneider and Przewlocki, 2005). The total time spent in social behaviour and the numbers of social contacts were measured (Niesink and Van Ree, 1989).

2.4. Statistical analysis:

Data for open field, elevated plus-maze, dark-light transition, depression as well as social interaction tests were analyzed by analyses of variance (AVOVA), using the general linear models procedure in SPSS[®] statistical software (SPSS, 2006). Statistical significance of difference between control and treated groups was determined by post hoc Tukey HSD test. A value of ($P < 0.05$) was considered

statistically significant. All data are expressed as mean \pm SEM.

3. Results:

3.1. Open field test:

The effect of tartrazine treatment on parameters of open field test was illustrated in Table 1. Rats under tartrazine effect increased significantly ($p < 0.001$) the mean covered distance in the open field test when compared with the control group. An anxiogenic like effect was obtained in tartrazine-ingested rats when compared to their counterparts in controls. Tartrazine-treated individuals presented a significant ($p < 0.05$) increase of rearing in peripheral area of the test. Treatment also significantly ($p < 0.05$) reduced numbers of central squares entered. A significant dose-dependent response was noted for numbers of grooming as well as stretch attending postures in tartrazine-exposed rats in comparison to their control ($p < 0.001$). The highest levels of these behaviours were recorded with high tartrazine dose. Moreover, a marked significant ($p < 0.01$) increase in fecal boli was also observed in rats following tartrazine treatment when compared to animals belonging to control group, regardless of incorporated dose.

3.2. Elevated plus maze:

The effect of tartrazine on measurement of elevated plus maze was demonstrated in Table 2. Regardless of the ingested dose, animals under tartrazine effects significantly ($p < 0.05$) diminished the numbers of entries in the open arms of the maze, accompanied with significant increase of this

measure in the closed arms. Regarding time spent in the open arms, tartrazine was significantly successful in endorsing an aversive dose-related effect since the shortest time spent in open arm was recorded with high tartrazine group.

3.3. Dark-light transition test:

A similar pattern of effects as those displayed in the elevated plus-maze was obtained in rats submitted to the dark-light transition test (Table 3). Statistical analysis showed that time spent by tartrazine-treated rats in the light compartment was significantly ($p < 0.001$) diminished, while increased in the dark compartment compared to control counterparts.

3.4. Forced swim test:

Immobility time during forced swim test was shown in Table 4. This measure was increased significantly ($p < 0.001$) in rats challenged with high dose of tartrazine compared to control rats.

3.5. Social interaction test:

Measurements of social interaction test in rats were presented in Table 5. Exposure to tartrazine significantly ($p < 0.001$) affected social interaction parameters as indicated by reduced time engaged in social behaviour with decreased numbers of social contacts as well. Although administered dose of tartrazine showed no significant change in time spent in social interaction, a marked significant dose response was noted for social contacts numbers ($p < 0.01$) showing less contacts with higher dose.

Table 1. Effect of tartrazine on the behaviour of rats in the open field test.

3. Discussion:

The present study elucidated the effect of tartrazine on open field locomotor activity in adult male Wistar rats. Tartrazine-treated animals significantly displayed higher levels of ambulation, a measure of hyperactivity, as indicated by increased numbers of crossing squares. Our findings are in accordance with previous scientific research reporting an association between behavioural deficits in young children in form of overactive, impulsive and inattentive behaviour and synthetic food colours (Boris and Mandel, 1994; Overmeyer and Taylor, 1999; Schab and Trinh, 2004; McCann et al., 2007). In contrast to our results, Tanaka (2006) demonstrated no link between tartrazine and hyperactivity in mice offspring. This discrepancy in results might be attributable to the different inoculated doses. Tartrazine-induced hyperactivity might be explained on the basis of zinc chelating property of tartrazine. Zinc depletion was found to be one of the potential causes of childhood hyperactivity following exposure to tartrazine (Ward et al., 1990). In addition, the formerly reported implication of azo dyes in motor system affection in mammals through dopamine pathways might further clarify the current noticeable hyperactivity in rats (Silbergeld and Anderson, 1882; Mailman and Lewis, 1983).

Anxiety in rats can be measured by behavioral reactivity to non-social or social stressors (Kim et al., 2004). These behaviors were compared by performing the open-field, elevated plus maze and the light-dark transition tests (non-social) as well as social interaction test (social). With regard to the present study, it is important to note that most of the behavioural models cited above have mainly been used in the studies on the neurobiological mechanisms implicated in the production of fear and anxiety elicited in animals exposed to aversive situations (Rodgers, 1997; Rodgers and Dalvi, 1997; Menard and Treit, 1999).

In our study, tartrazine caused a significant increase in the anxiety levels of rats in all three anxiety models employed. Regarding anxiety measurement in the open field test; numbers of rearing against the wall, central squares entered, grooming, stretch attending posture (risk assessment) as well as fecal boli, all parameters were greatly influenced by ingestion of tartrazine. Here, tartrazine prominently increased rearing activity regardless of the incorporated dose in rats. Rearing response against periphery has been proved to reflect higher levels of anxiety in rats (Anderson and Hughes, 2008). Again regardless of the administered dose, tartrazine-exposed rats showed increased entries of central squares in the open field. Frequent entries of central squares have been reported to indicate curious

animal with lower levels of anxiety (Frye et al., 2000). Supporting evidence for highly anxious rats in the current study derived from increased grooming activity. Moreover, expression of grooming behaviour was greatly affected by the administered dose where high doses of tartrazine were accompanied by increased grooming responses. Grooming has been validated as indicator of anxiety (Negishi et al., 2005). Risk assessment in the form of stretch attending posture was also found to increase after tartrazine exposure in rats. Higher frequency of these postures was reported to indicate anxious state of individuals (Blanchard et al., 2001). Where fecal boli were shown to be a sensitive measure for anxiety state of animals (Singer et al., 2005; Reolon et al., 2006), present administration of tartrazine was shown to enhance defecation. In light of the above mentioned observations, exposure to tartrazine was noted to induce anxiety state in rats. After ingestion of tartrazine, humans were proved to develop anxiety (Rowe and Rowe, 1994; Ansari and Mosayebzadeh, 2011).

Because of rats' innate fear of height and openness, rats tend to remain longer in the enclosed arm (Treit et al., 1993). Data derived from elevated plus maze further affirmed the previously observed effect of tartrazine on anxiety-related behaviours during open field test. Regardless of administered dose, decreased visits for open arms of elevated plus maze were recorded in our study after exposure to tartrazine. However, a dose-dependent effect of tartrazine on time spent in the open arms was evidently shown, where the less time was observed with high dose-administered rats indicating that they avoid this aversive region of the maze as reported in other studies (Bhattacharya et al., 1995; Schulteis et al., 1998). Therefore, time elapsed in the open arms might be considered as the more sensitive index for anxiety than number of visits.

The light-dark test has been used to assess the anxiogenic effects of multiple classes of drugs (Jonkman et al., 2005; Kliethermes, 2005). Our measurements of dark-light transition test also support the former observation of tartrazine-induced anxiety-like responses, where marked diminution in time spent in light compartment was noticed with tartrazine-exposed rats.

The forced swim test measures behavioural despair in rodents, and is generally used to study depression (Raghavendra et al., 2000). Currently, data of forced swim task revealed that tartrazine-exposed animals exhibited higher immobility; an index of depression-like behaviour (Sanchez and Meier, 1997), as a response for increased levels of stress reaction. Further support derived from earlier human study for Southwick et al. (2005), where

elevated cortisol in response to chronic stress was associated with increased manifestations of depression. The role of tartrazine in modulation of depression response has been formerly outlined in children where ingestion of tartrazine showed clinical depression, migraines and sleep disturbance (Rowe and Rowe, 1994). In addition, Novembre et al. (1992) reported two cases of unusual reactions to food additives (Tartrazine and benzoates) involving mainly the central nervous system (headache, migraine, over-activity, learning difficulties and depression).

Since many social disorder models in rodents are linked to human social deficits syndrome, social interaction test has been implemented in the current study. A profound reduction in time engaged in social interaction was observed in this work accompanied with decreased frequency of social contacts following exposure to tartrazine. The most interesting finding was the dose-related reducing effect on bouts of social contacts. These antisocial-related findings confirm our formerly reported results for increased hyperactivity, anxiety and depression in tartrazine-treated rats. Holmes et al. (2001) stated that presence of hyperactivity and inattention are the most highly related predisposing factors for presentation of antisocial behavior. Aberrant social behaviours or low levels of social interaction are symptoms of several psychiatric disorders, including anxiety, depression and social phobias (Crawley, 2007). Where serotonin system is important in the pathophysiology of psychiatric disorders including mood and anxiety, healthy levels of serotonin is essential to promote balanced mood (Millan, 2003; Dayan and Huys, 2008). The hippocampal serotonergic alterations have been reported to play an important role in control of anxiety, depression and other mood disorders (File et al., 1996, 2000). 5-hydroxytryptophan (5-HTP), a substance that is created naturally in the body from the amino acid tryptophan, has been shown to elevate the neurotransmitter serotonin naturally in the brain helping with depression and other mood disorders (Feurte et al., 2001; Moreno et al., 2006). Tartrazine has been found to diminish the ability of vitamin B6 to function in critical biochemical pathways such as tryptophan/serotonin metabolism (Bender, 1999; Meletis, 1999; Russo et al., 2003). This dysfunctional serotonin system might enlighten the noticeable tartrazine-imposed modulation in anxiety and depression disorders. Moreover, the underlying causes of these disorders are complex and may also involve other neurotransmitter systems including the noradrenalin and dopamine systems (D'Aquila et al., 2000; Ressler and Nemeroff, 2000). Serotonin can modulate the dopaminergic and noradrenalin

systems, and *vice versa* (Iyer and Bradberry, 1996; Esposito, 2006; Salomon et al., 2006).

In conclusion, the results reported herein potentially suggest the relevance of tartrazine in inducing harmful effects especially on behaviours related to anxiety and depression. This study also gives insight into the potential hazard of long term exposure to currently food-permitted colorants with increased incidence of psychological disorders and its co-morbidity impact on human health. Interesting avenues for further research on food colorants should be hearten in order to recognize their unexpected toxic effects and urge for prohibited use of harmful colours to ensure public health.

Abstract: Some of the truck producer involved in production of municipal-service vehicles make some modifications in the main chassis and permit overloading on it. With doing these modifications some special instructions must be considered such as: decreasing speed, strengthening the springs and chassis beams, and so on. Hence chassis vibrational behavior will change the dynamic behavior of automobile effectively, adding auxiliary chassis is an alternative trend to change the rigidity. But, the main question that must be answered is: Are natural frequencies of the modified chassis in suitable range? So, this paper investigates the vibrational characteristics of the chassis before and after strengthening. For this purpose, the modal analysis has been accomplished by the commercial finite element packaged ANSYS and natural frequencies and mode shapes have been determined. In addition, the relationship between natural frequencies and engine operating speed has been explained and, finally advantages of the modified chassis which leads to the increase of the rigidity with no much changes in natural frequencies, has been discussed. The results show that the road excitation is the main disturbance to the truck chassis as the chassis natural frequencies lie within the road excitation frequency range.

[Mousa Hadipour, Farshid Alambeigi, Ruhollah Hosseini, Reza Masoudinejad. A Study on the Vibrational Effects of Adding an Auxiliary Chassis to a 6-Ton Truck. Journal of American Science 2011; 7(6):1219-1226]. (ISSN: 1545-1003). <http://www.americanscience.org>.

Key words: Vibration, Modal analysis, Truck chassis, Auxiliary chassis, Finite elements.

1. Introduction

In Iran due to several reasons using truck-mounted sweepers is a preferred option in comparison to different types of compact street sweepers. Some of the companies involved in production of municipal-service vehicles install street sweeping equipments on trucks and launch their product to the market; by making some modifications in the main chassis of the truck and optimizing it for continental life in Iran. These equipments are shown in Table 1.

The mentioned equipments impose a considerable load on the truck and in order for the chassis to survive the loads some precautions must be taken. Also the chassis is bound to have the necessary rigidity for the loads. Adding double chassis known as auxiliary chassis and also changing the connecting bars are some usual tricks to enhance the rigidity. Such companies improve the stiffness and load bearing capacity of truck by installing an auxiliary chassis. This chassis is installed on the main chassis, stretching from the back-end up to the cabin of the truck. Using this method in addition to increasing chassis rigidity, chassis mass will increase and here we face the challenge: how do the car's dynamic behavior change with simultaneous increasing in mass and rigidity?

The mentioned equipment impose a considerable load on the truck and in order for the chassis to survive the loads some precautions must be

taken. Also the chassis is bound to have the necessary rigidity for the loads. Adding double chassis known as auxiliary chassis and also changing the connecting bars are some usual tricks to enhance the rigidity. Such companies improve the stiffness and load bearing capacity of truck by installing an auxiliary chassis.

This chassis is installed on the main chassis, stretching from the back-end up to the cabin of the truck. Using this method in addition to increasing

chassis rigidity, chassis mass will increase and here we face the challenge: how do the car's dynamic behavior change with simultaneous increasing in mass and rigidity?

The dynamic response of simple structures, such as uniform beams, plates and cylindrical shells, may be obtained by solving their equations of motion. However, in many practical situations either the geometrical or material properties vary, or the shape of the boundaries cannot be described in terms of known mathematical functions. Also, practical structures consist of an assemblage of components of different types, namely beams, plates, shells and solids. In these situations it is impossible to obtain analytical solutions to the equations of motion (Fahi and Walker, 2004). Using numerical solutions and finite element methods will solve this problem.

Automotive industry is one of the biggest users of the technology of modal analysis. Truck chassis forms the structural backbone of a commercial vehicle. The modal behavior of car chassis is a part of most necessary information for the inspection into car's dynamic behavior. In this essay the modal analysis of modified truck chassis (combination of main chassis and auxiliary chassis) has been studied (Forouzan and Hosseini, 2010).

As a truck travels along the road, the truck chassis is excited by dynamic forces induced by the road roughness, engine, transmission and more. Under such various dynamic excitations, the truck chassis tends to vibrate [3]. Whenever the natural frequency of vibration of a machine or structure coincides with the frequency of the external excitation there occurs a phenomenon known as resonance, which leads to excessive deflections and failure. The literature is full of accounts of system failures brought about by resonance and excessive vibration of components and systems [4].

The global vibrational characteristic of a vehicle is related to both its stiffness and mass distribution. The frequencies of the global bending and torsional vibration modes are commonly used as benchmarks for vehicle structural performance. Bending and torsion stiffness influence the vibrational behavior of the structure, particularly its first natural [5].

The mode shapes of the truck chassis at certain Natural frequencies are very important to determine the mounting point of the components like engine, suspension, transmission and more. Therefore it is important to include the dynamic effect in designing the chassis [3].

Fig. 1 A view of truck

Many researchers carried out study on truck chassis. Vasek et al. (1998) have analyzed a truck dynamically. In their method in addition to simulating truck with finite element packaged ANSYS and being sure that structure vibrational modes are in appropriate range, they vibrationally analyzed it. Yuan Zhang and Arthur Tang (1998), compare natural frequencies of a ladder chassis with finite element and experimental methods. Guo and Chen (2008), research into dynamic and modal analysis of a space chassis (complex 3-dimensional chassis) and analyses transient response using the principal of superposition.

This paper deals with a 6 ton truck chassis that includes natural frequencies and mode shapes. This chassis has been shortened by related companies for using in municipal service (street sweeper) and here we face the challenge and it raises the question: Are natural frequencies of the modified chassis in suitable range?

In the studied model unlike the most previous models, rivets and bolts have been modeled completely. Also shell element has been used for analysis. This element has better and more disciplined meshing in comparison with other elements and has the capability of gaining more accurate results with the same meshing containing the related 3-dimensional elements. Validity of the results has been verified by comparing the results of a similar model by the model proposed by Fui and Rahman (2007).

2. Truck chassis

In this article, a 6 ton truck chassis has been studied. This truck chassis is a ladder chassis and its longitudinal and cross connecting sections are channel shaped.

Automotive overviews are shown in Figs. 1 and 2 and Table 2 illustrate dimensions of studied truck. Chassis material is JIS-SAPH41 with 7800kg/m³ density, 520MPa yield strength, and 590MPa tensile strength.

The auxiliary chassis is bolted by using eight structural connectors which are placed asymmetrically on the main chassis and improves the stiffness of the system. The length of the main chassis is 567 cm (considering the 660 cm long initial chassis, some of which is cut) and it is 82.6 cm wide while the auxiliary chassis which has the same width and is 367 cm long, is placed on it. The vertical distance between the main chassis and auxiliary chassis is 26 cm. Figures 3 and 4 shown a view of

structural connector and a plan of auxiliary chassis, respectively.

Fig. 3 A view of structural connector

Fig. 4 A plan of auxiliary chassis

Fig. 5 Main chassis model.

Fig. 6 Modified chassis model.

3. Finite Element model

Truck chassis has been modeled with 4-node shell element in ANSYS. Numerical studies on simple hollow rectangular beam show that this element is suitable for creating and meshing the model and it yields accurate results. The element used has 4 nodes with 6 degrees of freedom and is appropriate for linear and nonlinear deformations and also large deflections. There are approximately 70000 elements in the model that has proved suitable in comparison with other cases, so that the error in each case is less than one percent. In Fig. 5 and Fig. 6 main chassis model and modified chassis model have been shown.

Model with appropriate accuracy and with considering bolts and riveted joints effects has been simulated. Meshes and constraints have been shown in Fig. 7. The boundary conditions are different for each analysis. In normal mode analysis, free-free boundary condition will be applied to the truck chassis model, with no constraint applied to the chassis model [3]. A free-free boundary condition has been chosen as it is much simpler to test experimentally in this condition, if required (Forouzan and Hosseini, 2010).

Fig. 7 Meshed chassis.

4. Modal analysis and results

Modal analysis has been performed after creating the chassis finite element model and meshing in free-free state and with no constraints. The results have been calculated for the first 30 frequency modes and show that road simulations are the most important problematic for truck chassis. In this analysis we have made use of subspace method in ANSYS.

Since chassis has no constraints, the first 6 frequency modes are vanished. 3 modes are related to the chassis displacement in x, y and z directions and 3 modes are related to chassis rotation about x, y and z axes. In Fig.8 related natural frequencies and mode shapes for chassis with maximum displacement in y direction in each mode, have been shown.

The first, second and sixth modes are the global vibrations, while the others are local vibrations. Local vibration starts at the third mode at 29.612 Hz. The dominant mode is a torsion which occurred at 7.219 Hz with maximum translation experienced by both ends of the chassis. The second mode is a vertical bending at 17.153 Hz. At this mode, the maximum translation is at the front part of the chassis. The third and fourth modes are localized bending modes at 29.612 Hz and 33.517 Hz. The maximum translation is experienced by the top hat cross member. The member also experienced big translation at fifth mode which is a localized torsion mode. The top hat cross member is the mounting location of the truck gear box. The sixth mode is the torsion mode at 38.475 Hz with maximum translation at both ends of the chassis.

Found natural frequencies from modal analysis of truck chassis, are used for determining the suitable situations for truck parts in working conditions. Figure 8 shows that twisting mode with the frequency of 7.219 Hz is the prevailing mode. Results of first 12 analyzed modes for main chassis are shown in Table 3.

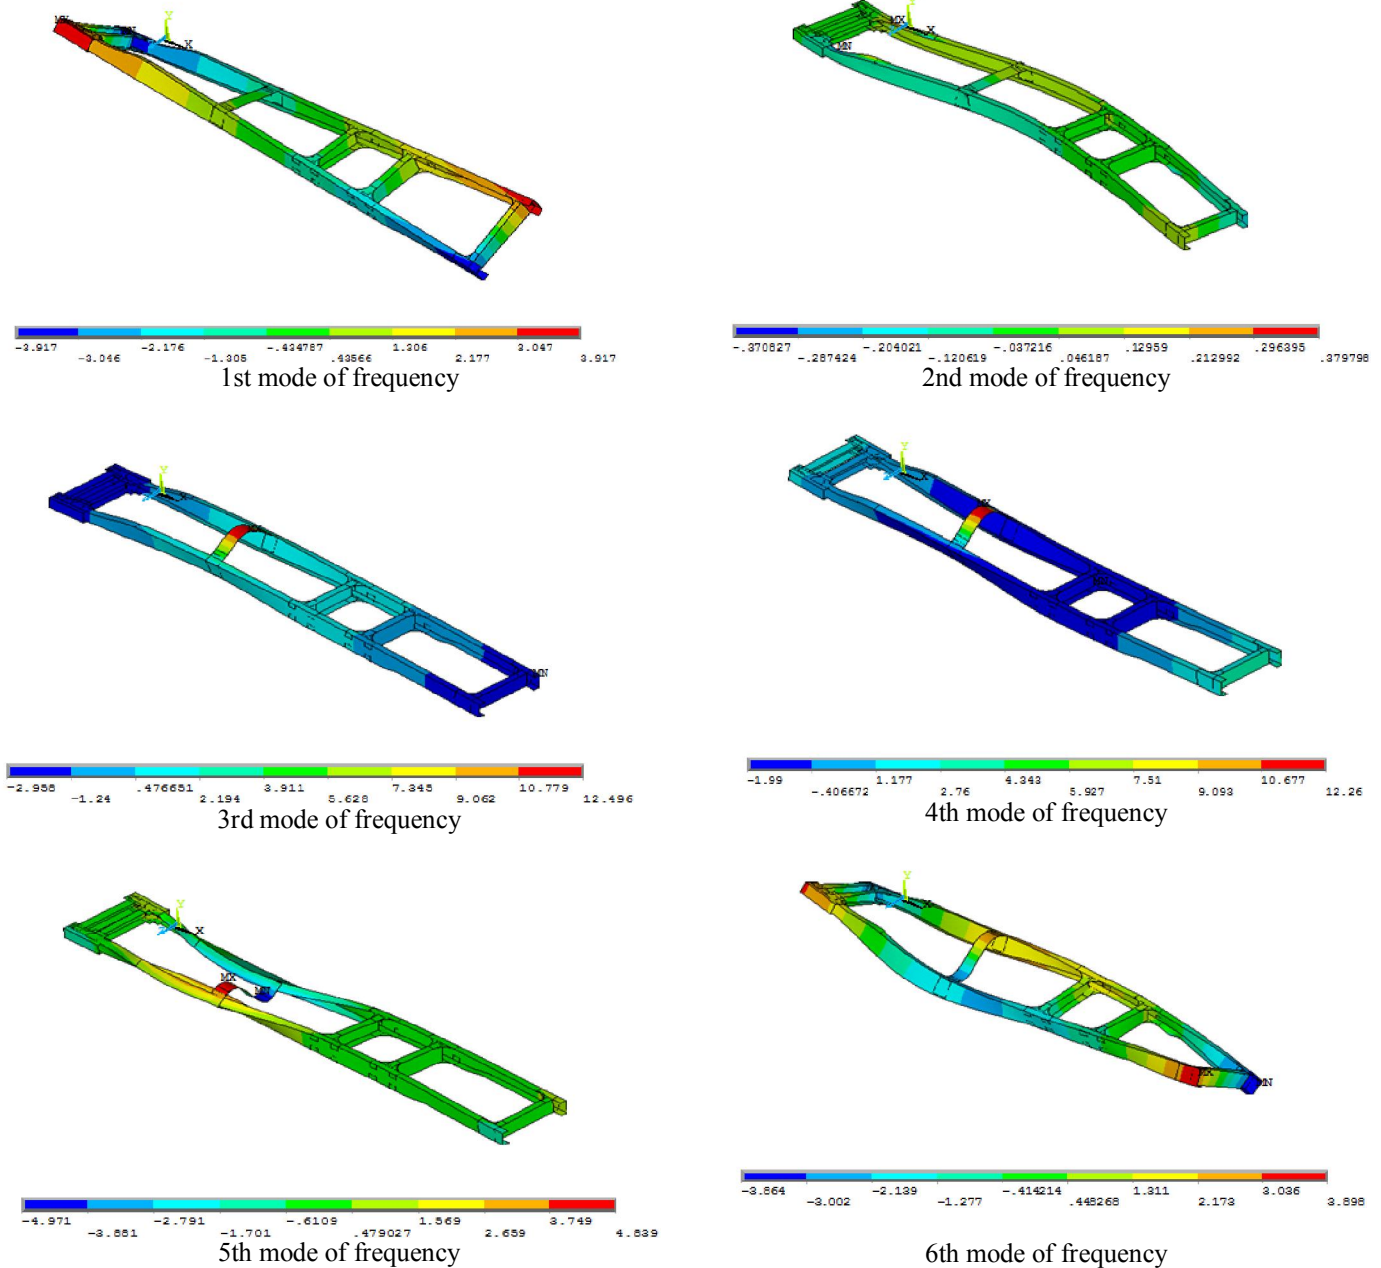

Fig. 8 Mode shapes and natural frequencies of truck chassis.

Because the analysis is in free-free state, the first 6 modes that have zero frequency aren't considered and mode numbers 7 to 12 in table 3 represent the first 6 modes of frequency.

It is necessary to notice that in usual, the first 6 modes of frequency (mode numbers 7 to 12 in Table 3 that have been shown in Fig. 8) play the main role in dynamic behavior of chassis and since the increasing noise effects and limited energy of motor to generate these frequencies, the effects of higher frequencies can be ignored.

Diesel engine is known to have the operating speed varying from 8 to 33 revolutions per second (rps) (Johansson and Edlund, 1993). In low speed idling condition, the speed range is about 8 to 10 rps. This translates into excitation frequencies varying from 24 to 30 Hz [3]. The main excitations are at low speeds, when the truck is in the first gear. At higher gear or speed, the excitations to the chassis are much less. The natural frequency of the truck chassis should not coincide with the frequency range of the axles, because this can cause resonance which may

give rise to high deflection and stresses and poor ride comfort. Excitation from the road is the main disturbance to the truck chassis when the truck travels along the road.

chassis. Figure 9 shows that twisting mode with the frequency of 9.462 Hz is the prevailing mode.

In practice, the road excitation has typical values varying from 0 to 100 Hz. At high speed cruising, the excitation is about 3000 rpm or 50 Hz. Mounting of vibration components of the truck on the nodal point of the chassis is one of the vibration attenuation methods to reduce the transmission of vibration to the truck chassis [3].

The mounting location of the engine and transmission system is along the symmetrical axis of the chassis's first torsion mode where the effect of the first mode is less. However, the mounting of the suspension system on the truck chassis is slightly away from the nodal point of the first vertical bending mode. This might due to the configuration of the static loading on the truck chassis.

In the following modal analyzing has been used for the modified chassis, in order to compare the main chassis and modified chassis. In Fig.9 related natural frequencies and mode shapes for chassis with maximum displacement in y direction in each mode, have been shown. Similarly the first, second and sixth modes are the global vibrations, while the others are local vibrations. Local vibration starts at the third mode at 27.610 Hz. The dominant mode is a torsion which occurred at 9.642 Hz with maximum translation experienced by both ends of the chassis. The second mode is a vertical bending at 16.271 Hz. Similar to the main chassis analysis, at this mode, the maximum translation is at the front part of the chassis. The third and fourth modes are localized bending modes at 27.610 Hz and 31.013 Hz. The maximum translation is experienced by the top hat cross member. The member also experienced big translation at fifth mode which is a localized torsion mode. The sixth mode is the torsion mode at 39.042 Hz with maximum translation at both ends of the

Results of first 12 analyzed modes for modified chassis are shown in Table 4. As a reminder it is mentionable that because the analysis is in free-free state, the first 6 modes that have zero frequency aren't considered and mode numbers 7 to 12 in Table 4 represent the first 6 modes of frequency.

In general the natural frequency can be calculated using the equation (1);

$$\omega_n = \sqrt{\frac{K}{m}} \quad (1)$$

where K and m stand for stiffness and mass respectively.

The equipment installed on the chassis of municipal-service truck increase the chassis mass which leads to the decrease of natural frequencies. Regarding the fact that the chassis stiffness and mass have both increased and considering equation (1) and noticing that the frequencies are in normal range and it has no considerable change, one can state that the mass increase due to the addition of auxiliary chassis is equally efficient on the natural frequencies as the increase in structural stiffness and thus eventually one can hardly find a change in natural frequencies.

By changing the place of gasoline tank and mounted equipments and other such considerations, attempt has been made to prevent coinciding the excitation force frequencies and natural frequencies. Otherwise resonance phenomenon occurs and the chassis undergoes destructive vibrations and if these two frequencies coincide, this phenomenon may lead to the structural failure of the chassis. As a reminder it

is mentionable that validity of the results is verified by comparing the results from a similar model with

the model proposed by Fui and Rahman (2007). Also their results confirm the results of this paper.

Fig. 9 Mode shapes and natural frequencies of the strengthened truck chassis.

5. Conclusion

The article has looked to changes of chassis dynamic behavior caused by change in usage and adding auxiliary chassis with finite element method. First six frequency modes of the main chassis and modified chassis that determine their dynamic behavior are below 40 Hz. For the main chassis frequencies vary from 7.219 to 38.475 Hz and for the

modified chassis they vary from 9.462 to 39.042 Hz. For the first two modes and sixth mode, the truck chassis experienced global vibration. The global vibrations of the truck chassis include torsion and vertical bending with 2 nodal points. The local bending vibration occurs at the top hat cross member where the gearbox is mounted on it.

Since chassis mass increases due to the installed equipment, the natural frequencies fall out of the natural range that can be compensated with increasing the chassis stiffness. Auxiliary chassis can increase the chassis stiffness. Using this method, we can prevent resonance phenomenon and unusual chassis vibration and place the natural frequencies in natural range.

Evaluation of Rubisco and PEP-carboxylase Levels as Affected by Salicylhydroxamic Acid within Developing Grains of Wheat

Davood Eradatmand Asli, Alireza Houshmandfar

Department of Agronomy and Plant Breeding, Saveh Branch, Islamic Azad University, Saveh, Iran
eradatmand@iau-saveh.ac.ir

Abstract: Effects of exogenous application of salicylhydroxamic acid (SHAM) on relative levels of ribulose-1,5-bisphosphate carboxylase/oxygenase (Rubisco) and phosphoenolpyruvate carboxylase (PEPC) were studied at different grains growing in the same spikelet of wheat (*Triticum aestivum* L. var. *PBW-343*). A concentration of 10 ppm salicylhydroxamic acid was applied at anthesis stage in five replications with the help of cotton plugs, which remained on ears of mother shoots (MS) for 48 hours. The labeled spikes were sampled five times, seven-day intervals started from seventh day after anthesis (DAA) up to 28th DAA, and at maturity. The spikelets were divided into two grain types included basal (bold) and apical (small). The salient point emerging through the use of salicylhydroxamic acid was that both bold and small grains showed an increase in relative levels of Rubisco and PEP-carboxylase at 21st and 28th DAA stages. The behavior of Rubisco in two types of grains showed an increase in its levels upto 14th DAA in bold grains and 21st DAA for smaller grains followed by a gradual decrease towards maturity. The smaller grains possessed a lesser *per se* levels of Rubisco per unit basis with the highest gap at mid ripening stage. The only exception was at maturity which the smaller grains possessed relatively higher levels of Rubisco than the bolder grains. Analysis of data with regard to PEP-carboxylase activity revealed more or less the similar pattern as that of Rubisco activity.

1. Introduction

An appraisal of parameters regulating cereals productivity divulges that their full potential to yield is still unrealized. One of the grey areas, which have remained untapped, is the host of physiological and genetical barriers of developing kernels to grow to an optima and their manipulation by desirable traits and methodologies. The potential up gradation of components constituting the total yield in wheat (number of productive tillers m⁻², grains per spike and 1000-grain weight), would help to raise the production substantially. Though, significant milestones have been achieved in the first two parameters the last component, the individual grain weight has eluded scientific investigations and rather paradoxically has declined with the advent of high yielding varieties.

A study into the physiology of grain yield shows the existence of variation among different varieties or genotypes or even the grains developing in the same ear (Asana 1968, Stoy 1969; Nautiyal *et al.* 1999; Yang *et al.* 2003; Gutam *et al.* 2008). It further discloses that the yield may be influenced by the availability of photosynthates to the developing sinks (Yin *et al.* 1998; Ravi *et al.* 2001; Sharma-Natu and Ghildiyal 2005; Foulkes *et al.* 2010). Various

sugar responsive genes in plants potentially affect the partitioning (Geiger *et al.* 1996) and have been stressed to be key determinant of plant productivity (Gifford *et al.* 1984). Dry matter partitioning also plays a paramount role in growth rate of sink organs (Heuvelink and Bertin 1994). Working on the grain growth in wheat and buckwheat variation among varieties was traceable to endogenous hormone production in variety vis-à-vis that in the ear (Dua and Sehgal 1981; Dua *et al.* 1990). A few biochemical components as advocated by Abrol *et al.* (1984), Hakaka (1998) and Hasan and Kamal (1998), might be of significance in determining sink efficiency and/or the grain yield. Since, the harvest index is the culmination of innumerable events, most of the view points on sink efficiency appears to be speculative and need a holistic approach in isolating obligatory events to produce the net assimilates. The revelation that the electron transport chain, in operation during biological oxidation, might find an alternate route without performing the target aim of creating proticity and may downgrade the overall impetus of meristems to grow by 10 to 25 percent (Siedow and Umbach 1995). Indeed, it has been reported that higher alternative respiration could be one of the reasons of lower growth of grains at distal

position in a spikelet (Sunita-Kumari and Ghildiyal 1997). It is, therefore, advocated that any attempt to interrupt this process may prove beneficial in improving productivity.

In the present study, it is proposed to analyze the relative levels of Rubisco and PEP-carboxylase as affected by specific inhibitor of salicylhydroxamic acid in different grains growing in the same spikelet of wheat.

2. Material and Methods

The investigation was conducted with a common bread wheat (*Triticum aestivum* L. var. *PBW-343*), which was sown in circular earthenware pots (50x30x30 cm) containing 35 kg of soil mixed with farmyard manure (4:1). Eight seeds per pot were sown and after 15 days, seedlings were thinned to two. Hoagland's nutrient solution (Hoagland and Arnon, 1939) was supplied to the pots. The plants were grown in a screen covered hall under otherwise natural conditions. A concentration of 10 ppm salicylhydroxamic acid was applied at anthesis stage in five replications with the help of cotton plugs, which remained on ears of mother shoots (MS) for 48 hours. The labeled main spikes were sampled five times, seven-day intervals started from seventh day after anthesis (DAA) up to 28th DAA, and at maturity. Grains were usually taken from three different segments in the ear. The labeled samples of grains were brought to laboratory and separated to two types of grains (small and bold) and the following biochemical analysis was carried out in the above aged grains.

PEPC was studied according to the method of Vance and Stade (1984) with some modifications as follows:

Extraction of the enzyme - Crude extracts were prepared by homogenizing 1 g fresh grain with acid-washed sand in a pre-chilled pestle and mortar in grinding medium (1 ml/1 g tissue) containing 50 mM tris-HCl (pH of 8.0), 50 mM MgCl₂, 5 mM, 2-mercaptoethanol and 1 mM EDTA. The homogenate was passed through four layers of cheese cloth, and filtrate centrifuged at 30,000 g for 30 minutes and the supernatant assayed for enzyme activities of PEPC. All the steps were carried out at 4°C.

Estimation of Enzyme - Phosphoenolpyruvate carboxylase was assayed spectrophotometrically at 30°C and 340 nm for at least 3 min in the assay media with a final volume of 1 ml. For the PEPC, the assay medium consisted of 10 mM NaHCO₃, 10 mM MgCl₂, 0.2 mM NADH and 4 mM PEP in 100 mM bicine-KOH buffer (PH of 8.5) optimized from Vance and Stade (1984).

Before placing samples in spectrophotometer 0.2 mM NADH was added as quickly as possible in to the test tube with a vigorous mixing well and the initial absorbance was recorded and thereafter every 30 sec for at least 3 minutes. Phosphoenolpyruvate carboxylase activity was expressed as $\mu\text{mole per min per gram fresh weight of sample}$. PEPC activity was calculated with decrease in absorbance for one minute and with the following formula:

$$\mu\text{moles per min } 0.2 \text{ ml enzyme extract} = \frac{\text{Absorbance decrease}}{\text{min}} \times 0.1613 \times 3 \text{ (volume of the reaction mixture in ml)}$$

Rubisco was studied radiometrically according to the method of Bravdo and Pallas (1982) with some modifications, in terms of stopping the activity by glacial acetic acid. The enzyme is made to utilize labelled CO₂ as the substrate and the radioactivity in the products is counted as a measure of enzyme activity.

Extraction of the enzyme - Grains samples, weighing one gram were homogenized in chilled mortar and pestle. Enzyme was isolated in 8 ml medium of 100 mM tris-HCl buffer (pH of 8.0) containing 5 mM DDT, 20 mM MgCl₂, 0.5g PVP and 0.2 mM EDTA. The crude extract was filtered through four layers of muslin cloth and the filtrate was then centrifuged at 20,000 g for 30 minutes at 4°C. The supernatant was collected as the enzyme source.

Estimation of the enzyme - In a total volume of 250 μl , the assay mixture for Rubisco contained 98 mM tris HCl (pH of 7.8), 20 mM MgCl₂, 20 mM NaH¹⁴CO₃ (specific activity 48.1 mci/m mole, activity 0.5 mci, obtained from BARC; Bombay). 20 μl of crude enzyme was incubated with all components except RuBP for 5 minutes at 30°C and the reaction was initiated by addition of RuBP. After 2 minutes the reaction was stopped by adding 250 μl of glacial acetic acid. Blank reaction mixture was prepared by adding all ingredients except RuBP. The samples were kept overnight in fume hood. Next day known volume was taken and added 10 ml of scintillation medium. Counting was done in liquid scintillation counter (Packard Tricarb, Liquid Scintillation Spectrometer).

Scintillation liquid was prepared by the method of Bray (1960). According to this 4 gm P.P.O., 0.2g PoPoP and 10 g naphthalene were dissolved in 1 liter of toluene. For dilution of NaH¹⁴CO₃ solution, 1.0 ml of NaH¹⁴CO₃ (0.5 mci) was diluted with cold NaHCO₃ solution so

as to give a final concentration of 100 mM. Rubisco activity was estimated as:

$$(\text{CO}_2 \text{ fixed}) \text{ dpm} \cdot \text{g}^{-1} \text{ f.w.} \cdot \text{h}^{-1} = \frac{\text{dPm} \times V_1 \times 60}{V_2 \times t \times w}$$

Where net dpm is the disintegrations per minutes minus back ground counts, V_1 is the volume of assay system, V_2 is the amount loaded for counting, t is the reaction time and w is the weight of the sample.

3. Results

According to Figure 1, the inhibitor behaved in an enigmatic way and proved to be a promoter when being assessed under the criterion of dry matter accumulation in grains. During the earlier period of grain development, it had no significant effect thereby indicating that the underlying physiological process may not be in operation. Subsequently a significant increase in dry matter accumulation in both the types of grains at 21st DAA onwards up to maturity was noticed at both the concentrations of SHAM. The salient points emerging through the use of salicylhydroxamic acid were that (i) both bold and small grains showed a significant increase in dry matter from 21st DAA stage with its applications and (ii) in spite of the aforementioned increment gathered by grains, they continued to exhibit the disparity between them and at maturity the smaller grains still showed approximately 25 percent lower dry matter than the bolder grains.

Figure 1. Percentage of increase (+) in dry weight of grains at different location within developing grains of wheat (*Triticum aestivum* L. var. *PBW-343*) as influenced by salicylhydroxamic acid

The scrutiny of the data with regard to the effect of salicylhydroxamic acid on relative levels of Rubisco, the key enzyme regulating C fixation, presented a few interesting correlations. A look into the Figure 2 depicts the behavior of Rubisco in two types of grains

which showed an increase in levels of Rubisco upto 14 days in bold grains and 21 days for smaller grains post-anthesis stages followed by a gradual decrease toward maturity. Following by the application of salicylhydroxamic acid, both bold and small grains showed an increase in relative levels of Rubisco at 21st and 28th DAA stages (Figure 3). The two types of grains significantly possessed its differential levels. Analysis of the data revealed that the smaller grains possessed a lesser *per se* levels of Rubisco per unit basis with the highest gap at mid ripening stage. The exception was at maturity which the smaller grains possessed relatively higher levels of Rubisco than the bolder grains (43.3 percent higher in smaller grains) (Figure 6).

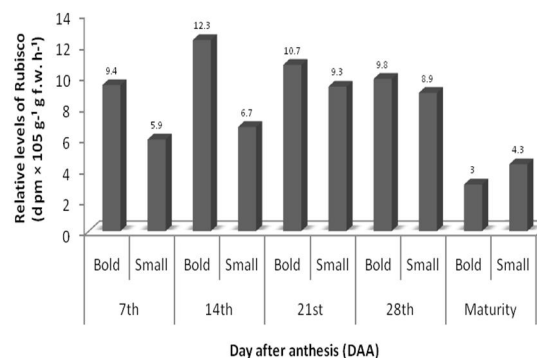

Figure 2. Relative levels of Rubisco ($\text{d pm} \times 105 \text{ g}^{-1}$ fresh weight h^{-1}) at different location within developing grains of wheat (*Triticum aestivum* L. var. *PBW-343*) as influenced by salicylhydroxamic acid

Figure 3. Percentage of increase (+) or decrease (-) in the level of Rubisco over control at different location within developing grains of wheat (*Triticum aestivum* L. var. *PBW-343*) as influenced by salicylhydroxamic acid

Analysis of data with regard to PEP-carboxylase activity revealed more or less the similar pattern as that of Rubisco activity

(Figures 4, 5 and 6). Its levels increased as the grains progressed upto mid ripening stage followed by a gradual decrease towards maturity (Figure 4). Following by the application of salicylhydroxamic acid, both bold and small grains showed an increase in relative levels of PEP-carboxylase at 21st and 28th DAA stages (Figure 5). With regard to its distribution in bold and small grains, was apparent that the bolder grains possessed relatively higher levels of PEP-carboxylase at 7th, 14th, 21st and 28th DAA stages of investigation. The higher quantum of distribution in bold grains was maximum at 14th DAA (44.2 percent lesser in smaller grains) and subsequent differences were to the tune of 11.3 and 8.3 percents short in smaller grains at 21 and 28 days post-anthesis stages respectively. At maturity the smaller grains possessed relatively higher levels of PEP-carboxylase than the bolder grains (20.8 percent higher in smaller grains) (Figure 6).

4. Discussions

The results bring forth, in no uncertain terms, the findings that the ear of wheat is a developing place for a definite number of grains which intern are separate biological entities endowed with their inherent potentials. This axiom was advocated by Abolina (1959) and is in line with the observations of innumerable workers (Cook and Evans 1978; Larsson and Hensen 1992; Wang *et al.* 1998; Yang *et al.* 2003). Nevertheless, the sequence of events, piloting the yielding ability, is the metabolic profile and if augmented through the use of plant growth regulators (Yang *et al.* 2000; Houshmandfar and Eradatmand-Asli 2011) or by imposing a shift in metabolic events (Dua *et al.* 1990) promotory effects are achievable (Hayashi 1961; Michael and Beringer 1980). In present context, the central point which came to light in the present endeavor is that an unusual path of aerobic respiratory chain (CN-resistant respiration) plausibly switches-on during the grain filling stage and if checked, through the immaculate use of salicylhydroxamic acid, can increase the relative levels of Rubisco and PEP-carboxylase in the grains. Of course, SHAM or regulator of alternate oxidase pathway was not successful in eliminating the disparities between the two types of grains.

Abstract: Pakistan is passing through a phase of severe energy shortage. To meet the challenge, Pakistan has started a couple of hydropower projects. One of these is Neelum Jhelum Hydro Power Project (NJHPP), which consists of three main components, one diversion dam at Nauseri on Neelum River, 2nd 33-km long tunnel of 82 M² cross sectional area for conveying water to obtain 420-M head and 3rd component is power house for generation of 969 MW power. Presently, the major issue of NJHPP is the selection of excavation method which should meet the fast completion of project due to energy crisis in the country & to avoid legal conflict with neighbor country. The selection of excavation method depends upon number of factors such as geology, tectonic setup, strength of rocks, hydro geological conditions of the area, geometry of the tunnel and many other factors. In this study, large number of samples of rocks were collected from the project area and analyzed. On the basis of present work three methods, Drill and blast, excavation through Road Header & excavation through Tunnel Boring Machine (TBM) have been evaluated to determine the suitability for this project. Apparently, the existing status indicates that there is no major problem in the use of drill and blast and road header excavation method except their slow advancement rate. However to meet the fast excavation requirement for achievement of the completion target in 2014, TBM is the only left over option. The results of the strength and the other parameters of rocks are supporting TBM except the disaster expected through the potential fault planes which run along the way of the tunnel & convergence pressures of mud rocks. It is suggested that detail geological investigation should be carried out along the tunnel route to support the final decision for selection of TBM.

[Mohammad Saleem Khan, Department of Geological Engineering, University of Engineering and Technology, Lahore Pakistan. Journal of American Science 2011;7(6):1232-1236]. (ISSN: 1545-1003). <http://www.americanscience.org>.

Keywords: Excavation method, geology, tectonic setup, strength of rocks, geological investigation

1. Introduction

Pakistan is facing severe energy crisis due to increase in demand and reduction in storage capacity of hydropower producing reservoirs. After the construction of Tarbela Dam in 1974, no large scale project could be initiated over the passed 35 years except Ghazi Brotha Hydral Power Project in 2003. Due to lack of planning and mismanagement day by day, the demand remained increasing and no cheap electricity project could be started. Few expensive options were adopted by the Government with installing thermal Power Projects. Ultimately, the Government issued vision 2025 program in 2000, wherein the stress was to exploit indigenous resources such as Hydropower and coal. Hence, Neelum Jhelum Hydropower project commenced since 2009 to overcome the power shortage.

Neelum Jhelum Hydropower project is located in Muzaffarabad, Azad Jamu and Kashmir (Figure 1). It is composed of a diversion dam at Neelum River, 33 km long tunnel and a power house at Jhelum River. Approximately 280 m³ per second of water will be utilized from Neelum River through a tunnel of cross sectional area 113.5 m² (revised) which will pass under Jhelum River and again release water into Jhelum

River which meander and gain a total head of 420.5 M from intake.

According to feasibility report by Nonconsult (1996) a concrete gravity dam 135 m Long and 47 m high is being constructed on Neelum River at Nauseri which is designed for over-topping. The dam will create a head pond of 8 million cubic meters which will allow a peaking reservoir of 2.8 million cubic meters to meet daily peaking of power for more than 4 hours.

The total length of head race tunnel is 28.5 km., wherein 15.1 km stretch of the tunnel from the Nauseri be constructed as a twin tunnel system each with x-section of 43 m². The remaining head race tunnel down to the surge chamber will be a single tunnel having x-section of 82m². The tunnels are shot Crete lined with a concrete invert. The tunnel crosses approximately 380 m below river bed.

The present status of the Neelum Jhelum Hydro Power Project is that 7 adits have been completed 80% of designed length and head race tunnel upto 1.5 km by the drill and blast method. Later these adits will be used as access tunnels for removal of excavated material.

Figure 1: Location map of Neelum Jhelum Hydro Power Project indicating Dam Site, Tunnel Route and Power House (Norconsult, 1996)

The project is required to be completed in 2015 or possibly in 2013 to achieve two targets. Firstly early completion will provide cheap hydropower of 969 MW and secondly to avoid legal complications in the light of Indus Water Treaty.

To achieve the target and objectives of an early completion three tunnel methods in the light of various studies performed by researchers (Doyuran, 1997., Singh, 1998., Dick, 1995., Bell, 2007 & Kaneko, et al., 2002) are being evaluated in this study.

2. Geology

The geology of the project area is predominantly composed of Murree Formation of Miocene age. Shah (1997) reported that, "the formation is composed of a monotonous sequence of dark red and purple clay and purple grey and greenish grey sandstone with subordinate intraformational conglomerate, the basal strata of the formation consist of light greenish grey calcareous sandstone and conglomerates with abundant derived Eocene larger foraminifers". Geologically the project area can be divided into two zones. The dam site and intake reservoir nearby the village of Nauseri is the only area where two formations are exposed. On the right side of Neelum River and intake reservoir Punjal Formation is exposed which is lithologically composed of volcanic elastic rocks. In the rest of

whole Project area the tunnel and power house only one formation is exposed i.e., Murree Formation.

2.1 Punjal Formation

This formation is only exposed in the reservoir area and composed of three rock units, Green Sandstone, Marble and Limestone. Only diversion tunnel has been successfully excavated in this formation by drill & blast method.

2.2 Murree Formation

It is exposed through out the project area except the dam site & reservoir area. The Lithology of the Murree Formation is composed of alternate beds of hard and soft rock. Four major rock units have been identified as sandstone, siltstone, shale and mudstones (Mubashir, et al., 2009, Khan, et al., 2010).

3. METHODOLOGY

As the execution work of the tunnel has already been commenced since 2009, the methodology is comprised of the field data collection through reconnaissance survey and laboratory testing.

3.1 Field Data Collection

Rock samples were collected from the adits where excavation through Drill and Blast Method was under progress. Geological Mapping and

discontinuity survey were also carried out in two adit to assess the field condition and identification of joint pattern.

3.2 Lab Testing

To determine the engineering geological properties of the various rock units through which excavation will be carried out for tunnel, following tests were performed on thirteen samples adopting standard methodology.

Uniaxial compressive strength, dumping constant, slake, durability, Atterberg Limits and clay activity.

4 Criteria adopted for evaluation of Excavation Methods

Generally, the tunnel excavations and other large diameter excavations are based on examination of following parameters:

1. Geology and Tectonics of the area
2. Joint pattern
3. Geometry of the tunnel
4. Strength parameters
5. Porosity and permeability
6. Water conditions
7. Economic parameters

In the light of above parameters, rock samples were collected from the project area and analyzed to find out rock properties necessary for selection of excavation method. Hence, on the basis of various field and laboratory testing, following three excavation methods have been evaluated accordingly.

1. Drill and Blast Method
2. Road Header
3. Tunnel Boring Machine (TBM)

4.1 Drill and Blast (D&B) Method

Presently, Drill and Blast method has been adopted for excavation of tunnels in the Neelum Jhelum Hydro Power Project and approximately 7.3 kms tunnel (in total) have been successfully completed. Our results regarding strength (Table 1) and other parameters given in Tables 2 & 3, are also supporting this method except slow progress.

4.2 Boom Type Machines (Road Header)

A variety of tunnel excavators are available in the market. The selection of tunnel excavation depends on the strength of the rock and diameter of the tunnel to be excavated. Mainly two types of road header are being deployed for tunnel excavation. For medium to hard rocks ripping type road headers are suitable where as for soft geology milling type road headers are used. Generally compared to D&B method for medium size tunnel average rate of progress per day is of 30% more by road headers compared to drill and blast method..

Normally road headers are no good for working in areas where compressive strength of rock is greater than 14 KSI. Some of our rock units have high compressive strength as 94 MPa, where excavation may be problematic through road header.

Table 1: Uniaxial Compressive Strength

Sample No.	Strength (MPa)			Average Value of UCS (MPa)
	First sample	Second sample	Third sample	
A	46.5	57.7	56.5	53.6
B	51.7	54.2	53.3	53.3
E	87.2	88.0	94.5	89.9
F	94.6	99.2	88.6	94.1
G	74.0	90.7	97.0	87.2
H	77.9	74.9	74.9	75.9
I	55.2	52.9	56.9	54.7
J	40.4	42.7	42.67	41.82
K	84.0	72.8	72.4	76.4
L	73.4	63.0	68.0	88.00
M	41.6	40.3	39.1	40.3
N	60.5	68.4	57.7	62.2
O	75.4	64.5	84.3	74.7
P	72.7	72.8	58.5	74.7
Q	17.0	15.6	16.9	16.5
R	53.13	35.5	44.8	44.5

Taheri (2008) reported that, "one of the main limitations for using the boom type machines is high bit consumption according to high abrasive mineral (such as quartz content). Only few authors have worked on the correlation between abrasively and the mineral content of the rocks and the relationship is not fully understood by now." Our results show that quartz content are in highest ratios upto 85% among all the rock units exposed in the study area. This situation apparently does not favor and suit excavation through road headers. Probably due to this factor the Project Authorities of NJHPP have not considered adaptation of road header for this project.

4.3 Tunnel Boring Machine (TBM)

This method has advantage to achieve fast completion target and safety. The major limitation for the selection of this method is that of convergent soil which may stick the machine. Another potential hazard area for TBM is the presence of a number of faults, through which tunnel has to be crossed which need detailed investigation. The project authorities are actively considering this option to adopt for early completion of the project.

Table 2: Determination of Damping Constant Using Various Resonance Frequencies

R	Mudstone (Sheared)	25.97	13.35

The results given in Tables 4 & 5 to determine clay activity indicate that there is no threat of convergence of soft formation during excavation by TBM. These results are based on limited samples collected from adits, however the situation may be quite different where the tunnel passes through over burden of more than 1800 M along the course of tunnels which may increase convergence to

dangerous levels.

Although it is a costly option but the project authorities have recently decided to use TBM for major section of the tunnel to achieve fast completion of the project. Until now no detail geological investigations to meet the requirements for design criteria are available but investigations along the route of the tunnel are under progress.

5 Conclusion and Recommendation

The Drill & Blast method is working well except slow progress which can be accelerated to start tunnel excavation from a number of locations through access tunnels which are already complete. The road header method has not been considered useful by the project authorities due to high ratio of quartz content in sandstone formation.

Recently decision has been made by the project authorities to use TBM which requires detail investigations for its design. Special considerations are required after 2005 earthquake to accommodate the potential hazards associated with active faults through which tunnel will cross.

6 Acknowledgement

The field support by the Engineers of WAPDA & NESPAK in sampling and arranging access to tunnels for data collection is greatly acknowledged. The contribution of Qazi and Farrukh, B Sc students during the Laboratory testing is also appreciated.

Effects of salicylhydroxamic acid on relative levels of starch and total sugars in different grains growing in the same spikelet of wheat

Alireza Houshmandfar, Davood Eradatmand Asli

Department of Agronomy and Plant Breeding, Saveh Branch, Islamic Azad University, Saveh, Iran
houshmandfar@iau-saveh.ac.ir

Abstract: The effects of salicylhydroxamic acid on relative levels of starch and total sugars were studied in different grains (bold and small) growing in the same spikelet of wheat (*Triticum aestivum* L. var. *PBW-343*). The plants were grown in a screen covered hall under otherwise natural conditions. A concentration of 10 ppm salicylhydroxamic acid was applied at anthesis stage with the help of cotton plugs, which remained on ears of mother shoots (MS) for 48 hours. Labeled spikes were sampled five times, seven-day intervals started from seventh day after anthesis (DAA) up to 28th DAA, and at maturity. The application of salicylhydroxamic acid presented the unique observations. The inhibitor behaved in an enigmatic way and proved to be a promoter when being assessed under the criterion of relative levels of starch and total sugars. The salient points emerging through the use of salicylhydroxamic acid were that (i) both bold and small grains showed an increase in relative levels of starch and total sugars from 14th and 28th DAA stages respectively ($P < 0.01$) and (ii) in spite of aforementioned increment, they continued to exhibit the disparity between them and at maturity the smaller grains still showed lower starch and higher total sugars than the bolder grains.

1. Introduction

Starch is the major constituent of cereal's end product and is a measure of the activity of processes contributing to its deposition in the grain (Chinnusamy and Khanna-Chopra, 2003). Sucrose, the primary product of photosynthesis and assimilated carbon, acts as the main raw material for its formation (Porter and May, 1955). Berry *et al.* (1971) isolated, studied and compared the output of starch among triticale, rye hard red spring and durum wheat. They reported that the greatest percentage of starch occurred in the triticale flour samples as compared to wheat and rye. Jenner (1980) correlated the starch synthesis in endosperm to concentration of sucrose in tissue. Starch accumulation appeared to cease during development in the oat prior to the total dry weight accumulation, while soluble carbohydrates primarily sucrose and glucose remained at higher levels (Koch and Peterson, 1991). Black *et al.* (1996) studied starch in embryos of wheat and reported that its levels accumulated in the axis and scutella from 20th DAA to reach a maximum at approximately 35th DAA and subsequently it declined to a very low value in late maturation. According to Jeng *et al.* (2003) starch content was initially low but increased rapidly during maturation while reducing sugars, sucrose and fructose decreased

in two spring wheat cultivars. Jenner and Rathjen (1972) concluded that magnitude of photosynthesis is adequate to maintain the flow of sucrose into the wheat grains but flow of sucrose may be limited by the capacity of the processes transporting the sugars during the final stages of its passage into grains. Kumar and Singh (1980) showed that active starch synthesis started from 14th DAA onwards and continued until 35th DAA.

Many plant developmental, physiological and metabolic processes are regulated, at least in part, by nutrient availability. In particular, alteration in the availability of soluble sugars, such as glucose and sucrose, help regulate a diverse array of processes (Gibson, 2004). The accumulation of sugars in the storage cells is crucial for the size of grain. According to Sterans (1970) sugars constituted nearly 10 percent of dry matter of wheat aleurone cells. Paul *et al.* (1971) reported that reducing sugars were gradually converted into non-reducing forms during development in developing seeds of rice. Kerepesi *et al.* (2002) reported that the contents of reducing and non-reducing sugars decreased as grains matured and the contents of non-reducing sugars were higher than reducing at maturity stages in hard red spring wheat. They reported that the concentration of glucose and fructose decreased

while raffinose which appeared at later stages increased with maturity. Duffus and Rosie (1973) found changes in soluble reducing sugars and studied that reducing sugars remained low throughout development.

Singh and Singh (1982) noticed that total soluble sugars decreased during course of grain development in rice treated with IAA, GA₃ and kinetin. Caputo and Barneix (1999) have studied the relationship between amino acids and sugars export to the phloem in wheat. They showed that the sugar concentration in the phloem exudates was increased by higher light intensities, but there was no difference in the amino acid concentration of the phloem exudates and thus the amino acid to sugar ratio in the phloem decreased under high illumination. The present results suggest that amino acids can be exported to the phloem independently of the export of sugars.

In addition to affecting a number of developmental processes, sugars have been implicated in the regulation of a large number of genes (Koch, 1996). The α -amylase gene family provides a particularly well-characterized example of sugar-regulated gene expression. Given their biological function, it is, perhaps, not surprising that the expression of many α -amylase genes has been shown to be repressed by soluble sugars, such as glucose and sucrose, thus providing a mechanism by which starch breakdown may be regulated to provide an adequate supply of soluble sugars (Gibson, 2004). The regulation of α -amylase expression by sugars is complicated, occurring at multiple levels as well as via multiple response pathways that can be dependent on sugar concentration or its fluxes. The comprehensive works of Liang *et al.* (2001) and Gibson (2004) have shown that α -amylase expression has been regulated by sugars at both the transcriptional and post-transcriptional levels.

The alternative oxidising pathway is a non-proton motive 'bye-pass' to main electron transport otherwise in operation through the cytochrome pathway. Despite its wasteful nature, in terms of energy conservation, the pathway is ubiquitous throughout the plant kingdom. A small alternative oxidising gene family probably exists and its members are differentially expressed in response to environmental, developmental and other cell signals. The alternative oxidising pathway enzymes possesses tight biochemical regulatory properties that determine its ability to compete with the cytochrome pathway for electrons.

Studies show that alternative oxidising pathway can be a prominent component of total respiration in important crop species. All these characteristics suggest that this pathway plays an important role in metabolism and/or other aspects of cell physiology (McDonald *et al.*, 2002).

Depending on the plant species and growth conditions, 30 to 70 percent carbohydrates fixed in photosynthesis get respired on the day of its synthesis (McDonald *et al.*, 2002). The terminal part of the respiratory path, which starts with glycolysis, consists of the mitochondrial electron transport pathway, in which, among other components, two terminal oxidizing systems, cytochrome C oxidase or alternative oxidase may operate. The later branches from the main electron transport pathway at the ubiquinone pool and beyond the branch point, unfortunately does not contribute to ATP production. The energy conservation is less than maximal if a part of the respiration proceeds via this non-phosphorylating (alternative) pathway. Because of its energy wasting nature, it is most interesting (scientifically, as well as economically) to investigate under which conditions and to what extent alternative respiration is used, and how its activity is regulated.

Many reports have appeared, in which the activity of the alternative oxidase entity was assessed with the use of specific inhibitors of the cytochrome (e.g., CN⁻, azide, antimycin) or (e.g., SHAM, benzhydroxamic acid, propyl gallate) pathways (Lambers, 1997). It was shown that the alternative pathway became active at very high reduction levels of the Q pool (Dry *et al.*, 1989). There have been a few reports of this alternate oxidative pathway from some angiosperms and its values have been correlated with a few physiological parameters directly or indirectly associated with yield e.g., in *Vigna radiata* grown at 19°C the concentration of the alternative oxidase component increased over two-fold in both hypocotyls and leaves as compared to 28°C. This response could not be carried to *Glycine max* cotyledons (Gonzalez-Meler *et al.*, 1999). Ribas-Carbo *et al.* (2000) reported that in a chilling-sensitive maize cultivar, the activity of the alternative pathway was higher during the recovery period than in a less chilling-sensitive cultivar. According to Millenaar and Lambers (2003) the alternative pathway is inhibited more at low oxygen concentrations compared with the cytochrome pathway. Therefore, the alternative pathway

does not have a function at low oxygen concentrations.

The activity of the cytochrome pathway depends on the availability of inorganic phosphate and ADP. If plants are exposed to very low phosphorus supply, its concentration along with that of ADP may become very low. Therefore, it has been postulated that under these conditions the activity of the alternative pathway is increased relative to that of the cytochrome pathway (Gonzalez-Meler *et al.*, 2001). Some oxygen free radical scavenger enzymes (catalase and total peroxidase) are more active in P-deficient plants, while others do not change (ascorbate peroxidase and superoxide dismutase) (Juszczuk *et al.*, 2001). Restriction of the cytochrome pathway by phosphorus limitation causes an increase in the formation of oxygen free radicals, which can be prevented (partly) by more active alternative oxidase pathway.

While studying the development of grains at basal and distal positions within a middle spikelet of mother shoot of wheat, Kumari and Ghildiyal (1998) observed that lesser growth of distal grains was associated with higher rate of alternative respiration compared to proximal grains, thereby inferring that lesser growth at distal position in a spikelet may be linked to high alternate oxidase system. Gonzalez-Meler *et al.* (1996) reported elevated CO₂ concentration inhibited the salicylhydroxamic acid-resistant cytochrome pathway, but had no direct effect on the cyanide-resistant alternative pathway. This response may be indicative of a shift in plant metabolism and the increased energy demand resulting from higher photosynthetic rates under CO₂ enrichment (Woodward, 2002).

In the present study, it is proposed to analyze the relative levels of starch and total sugars as affected by specific inhibitor of salicylhydroxamic acid in basal and apical grains growing in the same spikelet of wheat.

2. Material and Methods

2.1. Experimental setup

The investigation was conducted with a common bread wheat (*Triticum aestivum* L. var. *PBW-343*), which was sown in circular earthenware pots (50x30x30 cm) containing 35 kg of soil mixed with farmyard manure (4:1). Eight seeds per pot were sown and after 15 days, seedlings were thinned to two. Hoagland's nutrient solution (1939) was supplied to the pots. The plants were grown in a screen covered hall under otherwise natural

conditions. A concentration of 10 ppm salicylhydroxamic acid was applied at anthesis stage with the help of cotton plugs, which remained on ears of mother shoots (MS) for 48 hours. Labeled main spikes were sampled five times, seven-day intervals started from seventh day after anthesis (DAA) up to 28th DAA, and at maturity. Grains were usually taken from three different segments in the ear. The labeled samples of grains were brought to laboratory and separated to two types of grains (small and bold) and the following biochemical analysis was carried out in the above aged grains.

2.2. Starch analysis

Starch contents were estimated by the method described by Hodge and Hofreiter (1962). The brief procedure is as follows:

(i) Extraction of Starch - One gram of powdered dry sample of grains was transferred to 100 ml of volumetric flask. The material was hydrated and gelatinised with 30 ml of distilled water by keeping the flask over boiling water bath for 30 minutes. The flasks were well stoppered so as to prevent any loss of water by evaporation. The flasks were cooled under running cold water for 10 minutes and 60 ml of 60 percent perchloric acid was added slowly with thorough agitation so as to avoid any momentary high concentration of acid. The mixture was allowed to stand, with occasional stirring, for 15 minutes and the volume were made up with distilled water. After shaking, the contents were allowed to settle. The supernatant was used for starch estimation.

(ii) Estimation of Starch - 5 ml of the above supernatant solution was pipetted out into 100 ml volumetric flask. To this, 6 ml of cold distilled water was added. The solution was made incipient alkaline with a few drops of 2N NaOH with the use of phenolphthalein as an indicator. The solution was made just acidic with a drop of 2N acetic acid till the pink colour disappears and to this, 2.5 of 2N acetic acid, 0.5 ml of 10 percent potassium iodide and 5 ml of 0.01 N potassium iodate were added for the colour to develop. The volume was raised to 100 ml and intensity of the colour was measured at 650 nm in a Bausch and Lomb Spectronic 20 using red filter. A single blank containing all the reagents was used to adjust the absorbance at zero. The unknown quantity was estimated from the standard curve prepared with tomato starch and results expressed as mg per grain.

2.3. Total sugars analysis

Total sugars were estimated by the method of Dubois *et al.* (1956) with some

modifications as follows:

(i) Extraction of total sugars - Fresh grains weighing 1 g at different intervals of time after anthesis were cut into small cubes of 1 sq. mm and taken into a vial containing 5 ml of 80 percent ethanol and stored overnight. The samples were extracted with boiling ethanol the next day. The supernatant was decanted into 50 ml beaker. The residue was repeatedly extracted 4 times with 80 percent boiling ethanol. The volume of the combined supernatant was made upto 25 ml with 80 percent ethanol and then centrifuged at 6000 g for 20 minutes. The supernatant so obtained was used for the estimation of total sugars.

(ii) Estimation of total sugars - Total sugars were estimated using the reagents included phenol 5 percent and concentrated H₂SO₄. A suitable amount of the supernatant (0.2 – 0.5 ml) was taken in a test tube and to this 1 ml of phenol reagent and 5 ml of concentrated H₂SO₄ were added and mixed thoroughly. The absorbance was recorded after 20 minutes of colour development at 490 nm. The total sugars content were calculated from a calibration curve prepared with glucose and expressed as mg per grain.

3. Results

3.1. Relative levels of starch and total sugars

All the grains, irrespective of their size or positions in an ear, revealed a positive correlation between their ages and the levels of starch (Table 1). The first five spikelets, constituting as proximal, the next ten and the last five spikelets as middle and distal segments respectively had their own characteristic variations with a common generalization that the bolder grains possessed a higher levels of starch than the smaller grains at all the stages of grain development. The disparity between the bold and small grains in the levels of starch was maximum at 7th DAA in all the three segments (44.8, 30.0 and 55.6 percents lesser in smaller grains than bolder grains in proximal, middle and distal segments respectively) and further the disparity tended to taper with maturity. Interestingly, during the initial phases of grain growth, there were significant disparities within the smaller grains amongst themselves whether growing at proximal, middle or distal segments, while on the other hand, bolder grains reflected insignificant differences amongst them.

The data on total sugars are also presented in Table 1. The total sugars increased upto third week after anthesis in small grains in

the proximal, middle or distal spikelets, while its values enhanced upto fourth week in the bolder grains in the same segments. Their values were significantly lower in the bolder grains as compared to smaller grains in all the segments by a margin ranging from 8.1 to 46.9 percents. These disparities were maximum around three weeks after anthesis and this generalization was true for all the three segments under (45.6, 46.9 and 46.3 percents higher in smaller than bolder grains in proximal, middle and distal segments respectively). Interestingly the gap amongst the bold and small grains tended to taper with the grains' progression to maturity.

Table 1. Levels of starch and total sugars (mg grain⁻¹) at different location within developing grains of wheat (*Triticum aestivum* L. var. *PBW-343*) as influenced by SHAM

Relative levels (mg grain ⁻¹)	Grain type	Day after anthesis (DAA)				Maturity
		7 th	14 th	21 st	28 th	
Starch	Bold	2.0 (+5.3)	12.8 (+39.1)	21.9 (+23.7)	31.2 (+20.5)	32.7 (+18.5)
	Small	1.4 (+7.7)	9.1 (+35.8)	17.9 (+27.0)	26.9 (+24.5)	28.3 (+22.5)
Total sugars	Bold	3.48 (+1.8)	4.26 (+2.2)	4.86 (+4.1)	4.64 (+10.0)	4.62 (+14.9)
	Small	4.74 (+1.9)	6.04 (+3.1)	7.08 (+6.9)	6.54 (+14.9)	6.10 (+18.9)

Values within parenthesis indicate percentage of increase (+) in the level of starch/total sugars over control

3.2. SHAM effects on relative levels of starch and total sugars

The application of salicylhydroxamic acid presented the unique observations. Ironically, the inhibitor behaved in an enigmatic way and proved to be a promoter when being assessed under the criterion of relative levels of starch and total sugars.

The salient points emerging through the use of salicylhydroxamic acid were that (i) both bold and small grains showed an increase in relative levels of starch and total sugars from 14th and 28th DAA stages respectively (Table 1) and (ii) in spite of the aforementioned increment, they continued to exhibit the disparity between them and at maturity the smaller grains still showed lower starch and higher total sugars than the bolder grains (Figures 1 and 2).

As apparent from the Figure 1, the relative levels of starch in bold and small grains showed a significant disparity with respect to its distribution in the two types of grains. In comparison to bolder grains, the smaller grains possessed significantly low levels of starch. The disparity was sustainable throughout the ontogeny of grains development with maximum gap at 21st DAA (30.0 percent lower than bold grains) with a recorded gap of 28.9, 18.3 and 13.8 percent at 7th, 14th and 28th DAA and

ending up with a final disparity of 13.4 percent at maturity, respectively.

Furthermore, as apparent from the Figure 2, the relative levels of total sugars in bold and small grains also showed a significant disparity with respect to its distribution in the two types of grains. In comparison to bolder grains, the smaller grains possessed significantly high levels of total sugars. The disparity was sustainable throughout the ontogeny of grains development with maximum gap at 21st DAA (55.7 percent higher than bold grains) with a recorded gap of 36.2, 41.7, 40.9 and 32.6 percent at 7th, 14th, 28th DAA and maturity, respectively.

Figure 1. Percentage decrease (-) in relative levels of starch in small grains over their counterparts bold grains as affected by SHAM

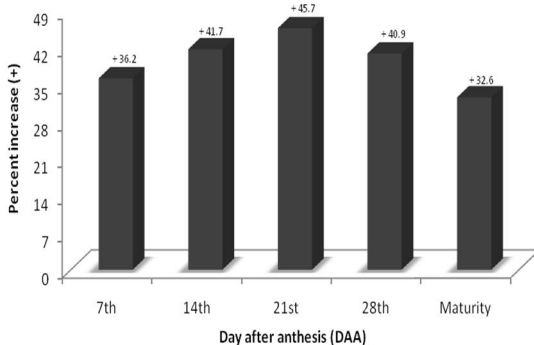

Figure 2. Percentage increase (+) in relative levels of total sugars in small grains over their counterparts bold grains as affected by SHAM

4. Discussions

We have investigated the relative levels of starch and total sugars as affected by salicylhydroxamic acid in basal and apical grains growing in the same spikelet of wheat. The results bring forth, in no uncertain terms, the findings that the ear of wheat is a developing place for a definite

number of grains which intern are separate biological entities endowed with their inherent potentials. This axiom was advocated by Abolina (1959) and is in line with the observations of innumerable workers (Cook and Evans 1978; Larsson and Hensen 1992; Wang *et al.* 1998; Yang *et al.* 2003). Nevertheless, the sequence of events, piloting the yielding ability, is the metabolic profile and if augmented through the use of plant growth regulators (Yang *et al.* 2000; Houshmandfar and Eradatmand-Asli 2011) or by imposing a shift in metabolic events (Dua *et al.* 1990) promotory effects are achievable (Hayashi 1961; Michael and Beringer 1980).

In present context, the central point which came to light in the present endeavor is that an unusual path of aerobic respiratory chain (CN-resistant respiration) plausibly switches-on during the grain filling stage and if checked, through the immaculate use of salicylhydroxamic acid, can increase the relative levels of starch and total sugars in the grains. Of course, SHAM or regulator of alternate oxidase pathway was not successful in eliminating the disparities between the two types of grains.

Abstract: Considering the comfortably establishing ad hoc networks, the use of this type of network is increasing day to day. On the other side, it is predicted that using multimedia applications will be more public in these network. As it is known, in contrary to best-effort flows, the transmission of multimedia flows in any network need support from QoS. However, the wireless ad hoc networks are severely affected by bandwidth, and establishing a QoS in these networks face problems. In this paper, we have proposed a thoroughly distributed algorithm to support the QoS in ad hoc networks. This algorithm guarantees the QoS of the real-time applications vis-a-vis each other and best-effort flows as well. The algorithm suggested in this paper dynamically regulates the Contention Window of the flows and serves the flows in terms of their requests QoS choosing the smallest CW in every node. This algorithm also uses the fixed and/or less stationary nodes for the transmission of real-time flows by increasing the QoS of the multimedia flows. This algorithm is preferred because it prioritizes the flows that are of the same class but have not obtained favorite QoS compared to other flows of the same class in addition to classifying the flows in the network and offering better services to the classes of higher priority. All this occur without the controlled packets forwarding and resource reserving and freeing method. We have proved the correctness of this algorithm using Markov's mathematical model.

1. Introduction

A wireless ad hoc network consists of a number of nodes communicating with each other on wireless links without infrastructure support. A multi hop ad hoc network is an ad hoc network in which the packets of a traffic flow are relayed by one or more intermediate nodes before they reach the destination. To support different types of real time applications, providing various quality of service (QoS) guarantees for multi-hop flows is an important issue in wireless ad hoc networks.

Many routing schemes and frameworks have been proposed to provide QoS support for ad hoc networks [1, 2, 3, 4, 5]. Among them, INSIGNIA [1] uses an in-band signaling protocol for distribution of QoS information. The term in-band signaling means that the control information is carried with data, and there is no separate control channel as opposed to another type of signaling called out-of-band signaling. INSIGNIA's architecture has several modules that are routing, in-band signaling, admission control, packet forwarding or scheduling, MAC protocol, etc. However, it is a stateful architecture because it uses soft state resource management scheme to utilize the resources.

SWAN [2] improves INSIGNIA by introducing an Additive Increase Multiplicative Decrease (AIMD)-based rate control algorithm. It supports service differentiation for real-time and

best-effort traffic. The SWAN's architecture handles both the real-time traffic and the best-effort traffic. Local rate control is used for handling the best-effort traffic of TCP, and a sender-based admission control is used for the real-time traffic of UDP.

Both [3] and [4] utilize a distance vector protocol to collect end-to-end QoS information via either flooding or hop-by-hop propagation. CEDAR[5] proposes a core-extraction distributed routing algorithm that maintains a self-organizing routing infrastructure, called the "core".

Most of the available algorithms do not have any control over the reception of the new flows. And some algorithms control the reception of the flows by exerting overhead on the network and exchanging control messages between the nodes in the path. These protocols do not attend to the fact that the transmission of the flows in a node may decrease the bandwidth of the available nodes in the scope of the node transmission. Therefore, these protocols only guarantee that the new flows will reach the desired QoS, but do not deed the point that the reception of the new flow may cause decrease in the QoS of the current flows. A solution to this problem is that the effort rate of the nodes in the path of the new flow transmission to obtain an environment be taken into account in deciding about the reception of the new flow. However, it is possible for some nodes in the

path not to be directly accessible for the decision-making nodes and to need multi-hop facilities. As it is seen, this method can exert too much overhead on the network. On the other hand, this method will not have desirable results for high rate of packets loss and movement of the nodes in the ad hoc networks. As such, the algorithms supporting the QoS must not be sensitive to the packet loss and must not exert much overhead on the network, which have been taken into account in our method.

Recently, other works have been proposed to improve the performance of MAC protocols and the support of service differentiation. Many of these approaches specifically target IEEE 802.11 [6]. For example, studies in [7,8,9,10] propose to tune the contention windows sizes or the inter-frame spacing values to improve network throughput, while studies in [7,11,12,13,14] propose priority-based scheduling to provide service differentiation. Most of this work utilizes different back-off mechanisms, different DIFS lengths, or different maximum frame lengths, based on the priority of the traffic.

However, the current status of the network and the QoS acquired by the flows are not given attention when these values are considered. In other words, these algorithms do not act fully automatically when priorities are given to the flows.

In this paper, a fully distributed algorithm is proposed for supporting the QoS of the flows in the network. Classifying the flows to delay-sensitive, bandwidth-sensitive and best effort, this algorithm differentiates the flows in the network in order to offer services.

This algorithm is preferred to others because, without any control packet, it gives much priority to the flows which are of the same class but have not obtained favorable QoS compared to other peer flows and tries to remove lagged QoS in these flows in addition to classifying the flows in the network. To put it another way, in addition to the type of the flows it attaches attention to the QoS different flows have acquired.

The rest of the paper is organized as follow. Section 2 is concerned with the QoS framework, algorithms and works done to classify the flows and support the flow QoS. In Section 3, the validity and properness of the suggested model is proved through Markov's Chain, and Section 4 is associated with conclusion.

2. QoS Framework

2.1. Desirable Network Modification

Our aim is to realize the QoS of the real time flows in the ad hoc networks vis-à-vis best-effort flows.

Many routing protocols in the ad hoc networks do not differentiate between fixed nodes, less mobile and mobile nodes for the transmission of the flows in multi-hop environment. In other words, there is an equal chance for the fixed, less mobile and mobile nodes to be chosen in the flow transmission though the fixed nodes and/or less mobile nodes offer better quality in the flow transmission. Thus, it is suggested fixed routers and/or less mobile routers be taken into account in special places of vast environments so that the transmission can be done with better quality. While best-effort traffic may be more tolerant to node mobility, the quality of real-time traffic will be significantly degraded and is likely to become unacceptable. The utilization of fixed wireless routers in these networks will greatly improve the quality of real-time traffic by the elimination of intermediate link breaks.

2.2. Find_Fix_Routers for real-time traffics

When a node wants to send a real-time flow, it must, first of all, call for Find_Fix_Router process in order to find a valid path. By a valid path, it is meant a path which is composed of fixed nodes and/or less mobile nodes and provides for the QoS of the desirable flow.

Find_Fix_Router process based on the modified AODV routing protocol. The modified protocol reflect the selection of stationary routes for real-time traffics. When a source node initiates route discovery for real-time traffic with strict quality requirements, only the fixed routers respond to the control packets by either forwarding the RREQ, or unicasting a RREP. The mobile nodes do not respond to these packets, unless they are the destination.

Find_Fix_Router also enables effective admission control when the network utilization is saturated. This requires accurate estimation of channel utilization and prediction of flow quality, i.e., throughput or transmission delay. The proposed QoS approach is based on model-based resource estimation mechanism, called MBRP[17]. By modeling the node back-off behavior of the MAC protocol and analyzing the channel utilization, MBRP provides both per-flow and aggregated system wide throughput and delay [16].

2.3. Prioritized medium access

In Ad hoc networks, priority scheduling algorithms are based on IEEE 802.11[6]. Currently, there are several approaches that propose to provide service differentiation to different types of traffic based on 802.11, by either assigning different minimum contention window sizes (CW_{min}),

Arbitrary Inter Frame Spacings (AIFS), or back-off ratios.

There are algorithms that differentiate between different flows through these techniques, but this differentiation is static. That is to say, it does not heed the network current status and current status of flows. Therefore reduces the usage efficiency of the network. So, we propose an adaptive scheme to manage trade-off. The basic idea is that, because the state of ad hoc networks can vary greatly due to mobility and channel interference, it is advantageous to adjust the back-off behavior according to the current channel condition and current QoS of flows.

To achieve service differentiation, as well as to adapt to the current network usage, we combine the collision rate and current QoS of flows with the exponential back-off mechanism in IEEE802.11. To do it, classifies flows into three types: delay-sensitive flows, bandwidth sensitive flows and best effort flows. Upon receiving the first packet from the flow related to one of the three classes, each node in the network builds a queue for that flow locally and without any overhead. Then it inserts this packet and subsequent packets related to that flow in this queue. The purpose of queuing each special flow is to manage and control the QoS obtained by each flow in every node and in the whole system consequently. The proposed algorithm does not let a flow obtain a quality higher than the requested quality. On the other hand, it tries to provide the quality requested by each flow. It is noted that contrary to real-time flows where a separate queue is built in every node for each flow, only a queue is built for all best-effort flows in every node. Figure 1 shows the queues built in each node to manage different flows.

Figure 1. Queues in each node (Network Layer)

2.4 Algorithms Used to Control QoS of Flows

In the algorithm proposed in this paper, the flows in the network are divided to three different

classes in order to differentiate the flows. As such, the level of offering services to the flows in the network is personalized with consideration of the type of the flow class and the QoS they have obtained. These three classes and the algorithms used to regulate the level of the service offered to the flows are discussed in this Section.

The delay-sensitive flows, such as conversational audio/video conferencing, require that packets arrive at the destination within a certain delay bound. The bandwidth-sensitive flows, such as on-demand multimedia retrieval, require a certain throughput. The best effort flows, such as file transfer, can adapt to changes in bandwidth and delay. Due to the different requirements of flows, each type of flows has its own contention window adaptation rule, as flows:

1) *Delay-Sensitive Flows*: For a delay-sensitive flow, the essential QoS requirement is end-to-end packet delay, which we call d .

To control delay, the d must be broken down into per-hop delay requirements. To maintain the aggregated end-to-end delay below d , each hop locally limits packet delay below its per-hop requirement. For this paper, each node is assigned with the same per-hop delay requirement, d/m , where m is the hop count of the flow. It is noted that the value of m is calculated through AODV routing algorithm.

$$CW^{(n+1)} = CW^{(n)} * \left(1 + \alpha \frac{d/m - D^{(n)}}{d/m}\right) \quad (1)$$

Where the superscript n represents the n^{th} update iteration, D denotes the actual peak packet delay at the node during a update period and α is a small positive constant ($\alpha=0.1$).

2) *Bandwidth-Sensitive Flows*: For a bandwidth sensitive flow, the essential QoS requirement is throughput. For control throughput it

is requires that at each node along the flow's route, the packet arrival rate of the flow should match the packet departure rate of the flow. In order for the rate of packet input to the node to be equal to the rate of packet output from the node, a queue must be used and its length must be managed. Therefore, it is suggested CW of the flows sensitive to bandwidth be calculated as follows:

$$CW^{(n+1)} = CW^{(n)} + \beta(q - Q^{(n)}) \quad (2)$$

Where q is a threshold value of the queue length that is smaller than the maximum capacity of the queue, Q represents the actual queue length and β is a positive constant ($\beta=1$). If Q is larger than q , the algorithm decreases CW to increase the packet departure rate to decrease queue length. If Q is smaller than q , the algorithm increases CW to decrease the packet departure rate and free up resources for other flows. As the queue size varies around the threshold value q , the average throughput of the flow matches its requirement.

3) *Best Effort Flows*: Best effort flows are tolerant to changes in service levels and do not have any hard requirements about bandwidth or packet delay. The purpose of updating the contention window size of best effort flows is to prevent best effort flows from congesting the network and degrading the service level of real-time flows and this is done by controlling the network congestion.

$$CW^{(n+1)} = CW^{(n)} \times (1 + \gamma(f - F^{(n)})) \quad (3)$$

Where f is a *congestion threshold* for idle channel time, F is the actual idle channel time and γ is a positive constant ($\gamma=0.1$).

When the average idle channel time F is smaller than the threshold value f , the network is considered congested and the contention window size of the best effort traffic is increased to avoid decreasing the service level of real-time traffic. On the other hand, if the network is lightly loaded so that the idle channel time is larger than f , the contention window size of best effort traffic is decreased so that the idle bandwidth can be utilized.

Later on, pseudo-codes related to the packet forwarding, packet receiving, CW calculation and back-off computation will be discussed.

When a node receives a packet do the following:

```

Receive_Packet(P)
{
  If (TypeOf(P)='Best-Effort') then
    If (there is no queue for Best-Effort flow) then
      Create a queue for Best-effort flow;
    Else if (p is the 1th packet of non B_E flow) then
      Create a queue for this flow;

```

```

  Add packet in specific queue;
}
  When a node want to send a packet do as
  following:

```

```

Packet_Send()
{
  Indicated which flow the smallest CW relates to.
  If (TypeOf(flow)='Real-Time') then
    Find_Fix_Routers();
    Remove a packet from queue;
    Send packet;
    Update queue pointers;
}

```

Each of nodes performs following instructions to calculating CW for each flow.

```

Calc_CW ()
{
  If (TypeOf(flow) = 'delay-sensitive' then
    
$$CW^{(n+1)} = CW^{(n)} * (1 + a \frac{d/m - D^{(n)}}{d/m})$$

  elseif TypeOf(flow) = 'bandwidth-sensitive' then
    
$$CW^{(n+1)} = CW^{(n)} + \beta(q - Q^{(n)})$$

  elseif TypeOf(flow) = 'best-effort' then
    
$$CW^{(n+1)} = CW^{(n)} \times (1 + \gamma(f - F^{(n)}))$$

}

```

The IEEE 802.11 use the following formula to compute the back-off related to each node:

$$Back-off = Rand[0, CW_{min} * Slot_Time, CW_{min} < CW < CW_{max}]$$

In order to compute the value of back-off for each node in this proposed algorithm, the rate of collision in the network besides the smallest CW must be taken into account. Thus, to compute the back-off, the equation (4) is proposed.

$$Back-off = Rand[0, (2^r + R_{col}) * CW_{min} * Slot_Time] \quad (4)$$

```

Back-off_Time()
{

```

```

  Get minimum CW(  $CW_{min}$  ) from network layer.

```

```

  Calculate Back-off time according to

```

$$Back-off = Rand[0, (2^r + R_{col}) * CW_{min} * Slot_Time]$$

```

}

```

Where R_{col} denotes the collision rate between a station's two successful frame transmissions and r is a positive number.

By applying Eq. (4), all flows dynamically manage their contention parameters to meet their own QoS needs. A real-time flow that did not get its required QoS in the past due to competition from other flows

decreases its contention window size so that statistically it will have a higher chance to obtain the channel in the future(Eq.(1),(2)). A best effort flow, on the other hand, increases its contention window size when the network is considered busy and hence releases the channel to the real-time flows(Eq.(3)). The random generated back-off counter ensures that the channel access attempts from different flows are spread out and do not cause a lot of collision. More importantly with attention to flow's current status, traffics with same class will have different back-off value when collisions occur. Specifically, after a collision occurs, low priority traffic will back-off for longer, and subsequently high priority traffic will have a better chance of accessing the channel. Contrary to [12], [15], in our proposed algorithm, no piggy-backed schedule information and neighborhood scheduling tables are needed. Therefore, there is no control message overhead imposed by our proposed algorithm.

In next section, the correct function of the proposed algorithm is proved.

3- Model Validation

In this section, we study the behavior of a single station with a Markov model, and we obtain the stationary probability π that the station transmits a packet in a generic (i.e., randomly chosen) slot time.

Bianchi uses a two-dimensional Markov chain of $m + 1$ back-off stages in which each stage represents the back-off time counter of a node, see Figure 2. A transition takes place upon collision and successful transmission, to a "higher" stage (e.g., from stage $i-1$ to stage i in Figure 3) and to the lowest stage (i.e., stage 0) respectively.

Figure 2. Markov chain model of back-off window size

Each state of this bi-dimensional Markov process is represented by $\{s(t), b(t)\}$, where $b(t)$ is the stochastic process representing the back-off time counter for a given station and $s(t)$ is the stochastic process representing the back-off stage $(0, 1, \dots, m)$ of the station at time t . This model assumes that in each transmission attempt, each packet collides with constant and independent probability p . In other words, p is the probability that, in a slot time, at least one of the $N - 1$ remaining stations transmits as well. If at steady state each remaining station transmits a packet with probability π , p can be written as:

$$p = 1 - (1 - \pi)^{N-1} \tag{5}$$

Let $\begin{cases} b_{i,k} = \lim_{t \rightarrow \infty} P\{s(t) = i, b(t) = k\} \\ i \in (0, m), k \in (0, CW_i - 1) \end{cases}$ be the

stationary distribution of the chain. A transmission occurs when the back-off time counter is equal to zero. Thus, we can write the probability that a station transmits in a randomly chosen slot time as:

$$\pi = \sum_{i=0}^m b_{i,0} \tag{6}$$

For the above Markov chain, it is easy to obtain a closed-form solution for $b_{i,0}$ as a function of p .

First, we can write the stationary distribution of the chain for $b_{i,0}$, $b_{m,0}$ and $b_{i,k}$:

$$\begin{cases} b_{i,0} = p^i b_{0,0} & 0 < i < m \\ b_{m,0} = \frac{p^m}{1-p} b_{0,0} \\ b_{i,k} = \frac{CW_i - k}{CW_i} b_{i,0} & 0 \leq i \leq m, 0 < k < CW_i - 1 \end{cases} \tag{7}$$

The first and second expressions in (7) account from the fact that $b_{i-1,0} \times p = b_{i,0}$ for $0 < i < m$ and $b_{m-1,0} \times p = (1-p)b_{m,0}$. The third equation can be

obtained considering the fact that $\sum_{i=0}^m b_{i,0} = \frac{b_{0,0}}{1-p}$

and taking the chain regularities into account (for $k \in (1, CW_i - 1)$), that is:

$$b_{i,k} = \frac{CW_i - k}{CW_i} \begin{cases} (1-p) \sum_{j=0}^m b_{j,0} & i = 0 \\ p \times b_{i-1,0} & 0 < i < m \\ p \times (b_{m-1,0} + b_{m,0}) & i = m \end{cases} \tag{8}$$

By imposing the normalization condition and considering Equation (7), we can obtain $b_{0,0}$ as function of p :

$$1 = \sum_{i=0}^m \sum_{k=0}^{CW_i-1} b_{i,k} = \sum_{i=0}^m b_{i,0} \sum_{k=0}^{CW_i-1} \frac{CW_i - k}{CW_i} = \sum_{i=0}^m b_{i,0} \frac{CW_i + 1}{2} = \sum_{i=0}^m b_{i,0} \frac{2^i W_{\min} + 1}{2} \tag{9}$$

$$= b_{0,0} \frac{W_{\min} + 1}{2} + \sum_{i=0}^{m-1} (b_{0,0} p^i \left(\frac{2^i W_{\min} + 1}{2} \right)) + \left(\frac{b_{0,0} p^m}{1-p} \right) \left(\frac{2^m W_{\min} + 1}{2} \right) = \frac{b_{0,0}}{2} \left[W_{\min} + 1 + \sum_{i=0}^{m-1} ((2p)^i W_{\min} + p^i) + \frac{p^m}{1-p} (2^m W_{\min} + 1) \right] = \frac{b_{0,0}}{2} \left[W_{\min} \left(\sum_{i=0}^{m-1} (2p)^i + \frac{(2p)^m}{1-p} \right) + \frac{1}{1-p} \right]$$

Thus $b_{0,0}$ can be written as:

$$b_{0,0} = \frac{2(1-2p)(1-p)}{(1-2p)(W_{\min} + 1) + pW_{\min}(1-(2p)^m)} \tag{10}$$

Finally, considering equations (6), (7) and (10), the channel access probability π of a node is derived as a function of the number of back-off stage levels m , the minimum contention window value W_{\min} , and the collision probability p :

$$\pi = \sum_{i=0}^m b_{i,0} = \frac{b_{0,0}}{1-p} = \frac{2(1-2p)}{(1-2p)(W_{\min} + 1) + pW_{\min}(1-(2p)^m)} = \frac{2}{1+W_{\min} + pW_{\min} \sum_{k=0}^{m-1} (2p)^k} \quad (11)$$

Considering equation 11, how a node obtains a channel and transmits a flow depends upon the rate of collision and CW in each node. That is to say, any node that faces less collision and has the smallest CW obtains the channel with high probability and embarks upon the transmission of its flows. For this reason, nodes can regulate the CWs related to their own flows and provide the desirable QoS. In the proposed, the CW related to the flows is regulated by means of Eq. (1,2,3). These algorithms are regulated such that they will increase its CW value quickly and provide other flows with the resources existing in the system if a flow obtains a resource more than the required resource at a time and obtains a QoS higher than the desirable QoS. Consequently, other flows will not face any limitations in obtaining resources. On other hand, any node which does not obtain it required resources and QoS at a point in time make much efforts to obtain the resources and compensate for the damages by decreasing its own CW and acquiring much back-off in order to obtain its desirable QoS.

Therefore, it is seen that the algorithm proposed in this paper shows a correct function in different conditions, in this algorithm, the flows help each other under some circumstances besides quarreling with each other for obtaining resources in order for all the flows in the network to obtaining required QoS.

4- Discussions

In this paper we introduce a new QoS support protocol that could be run in large-scale ad hoc networks, which this protocol is simple, fully distributed and use no control packets. An important benefit of this protocol is that it does not need resource reservation and therefore, it does not have the problems related to the use of in-bound and out-bound signals to reserve and free the resources, and the network bandwidth is not occupied by reserving and freeing the resources. This has caused this protocol be a light weight protocol that could be used in multi-hop ad hoc networks.

In the future, we will investigate the effect of different values α, β, f, r on the throughput and delay related to different classes.

Study of the Effects of Micronutrient Application on the absorption of macro- and micronutrients in the Soybean Cultivar Telar in the North of Iran

Abed vahedi

Department of Agronomy and Plant Breeding, Faculty of Agricultural and Natural Resources, Qaemshahr Branch, Islamic Azad University, Qaemshahr, Iran. E mail: av1790@hotmail.com

Abstract: In order to study the effects of applying the micronutrients zinc, boron, and manganese (which are added to the soil and sprayed on the crop) on the absorption of the macro- and micronutrients in soybean seeds, an experiment was carried out using the factorial design with the two factors of adding the micronutrients zinc, manganese, and boron to the soil and spraying them on the crop, with 16 treatments and four replications (a total of 64 trials). On the basis of the soil test which had been conducted, the required amounts of the micronutrients (40, 30, and 10 Kg.h of zinc sulphate, manganese sulphate, and boric acid, respectively) were added to the soil before seeding. In the spray treatments, zinc and manganese (0.30 %) and boron (0.20 %) were sprayed on the crop at the start of stem elongation and at flower bud formation. Results of the comparison of the means showed that the highest concentration of nitrogen (6.65 %) and phosphorous (0.18 %) in the seeds were obtained when zinc was sprayed on the crop, the highest potassium concentration in the seeds (0.92 %) was achieved when manganese was added to the soil, and the highest zinc concentration in the seeds (52.5 ppm) was observed when zinc was applied to the soil. These results also indicated that, among the treatments of spraying the micronutrients on the crop, the highest manganese concentration in the seeds (24.77 ppm) was obtained when manganese was sprayed on the crop, that the highest boron concentration in the seeds (46.58 ppm) was achieved when boron was added to the soil (and that this boron treatment had a statistically significant difference with the others). Comparison of the interaction effects of the data showed that the highest seed nitrogen concentration (6.72 %) was observed when zinc was sprayed on the crop, that the highest seed phosphorous concentration (0.22 %) was obtained when boron was added to the soil, that the highest seed potassium concentrations (0.93 % and 0.94 %) were achieved when zinc and manganese were sprayed on the crop, respectively, that the highest seed zinc concentrations were observed by adding manganese to the soil plus spraying zinc on the crop (55.33 ppm) and by adding zinc to the soil plus spraying zinc on the crop (55 ppm), that the highest seed manganese concentration (23.67 ppm) was obtained by adding zinc to the soil plus spraying manganese on the crop or by adding manganese to the soil plus spraying boron on the crop, and, finally, that the highest seed boron concentrations (44 and 41.67 ppm) were achieved by spraying boron on the crop and by adding manganese to the soil plus spraying boron on the crop, respectively

1. Introduction

Oil crops are among the important crop plants and their products form a part of daily food for people and feed for stock. Considering our population of 70 million, we need more than 1.1 million tons of edible oil each year. However, less than 14% of our annual oil consumption is produced in the country, and the rest must be imported from abroad (Anonymous, 2006).

Soybean (*Glycine max* [Merrill]) is one of the most important oil crops, and it has played an undeniable role in the production of edible oil in our country, especially in the province of Mazandaran. Soybean is planted in rotation after canola, wheat, and other fall crops, and produces a considerable quantity of good quality oil (seed oil content of 18 to 25%) and protein (seed protein content of 30 to 50 pp%) (Khajeh Pour, 2006). Optimal application of

plant nutrients has a considerable role in increasing the yield of soybean, and in improving its quality and the quality of its oil. Zinc deficiency is one of the most important and widespread micronutrient deficiencies in the world, and it causes a reduction in the yield of crop plants (Grewal et al., 1997; Cakmak, 2000). Soybean is also sensitive to boron deficiency (Victor et al., 1990), and this micronutrient plays a very important role in soybean seed formation and in increasing its oil content (Grant and Baily, 1992). Soybean is very sensitive to manganese deficiency as well, a condition common in neutral and alkali soils with high pH, and manganese deficiency causes soybean plants to be short and to have yellow leaves. Alley et al. (2008) reported that manganese absorption by soybean and soybean seed and oil yields increase when manganese is added to the soil and sprayed on the crop; and that manganese

deficiency has a negative influence on soybean seed oil content. Undoubtedly, optimal application of plant nutrients has a significant role in improving the yield and quality of soybean and of its oil. Since Mazandaran is the center of soybean production in the north of the country, the study of the way the application of micronutrients (added to the soil or sprayed on the crop) influences the absorption of macronutrients, such as nitrogen and phosphorous and potassium, and micronutrients, such as zinc and manganese and boron, is very important. Therefore, this study was conducted in the region of Dasht-e-Naz in Sari (in the province of Mazandaran) to investigate the effects of the application of the micronutrients zinc, manganese, and boron (and to compare the effects of their mode of application – i.e., whether they are added to the soil or sprayed on the crop) on the way macro- and micronutrients are absorbed by soybean.

2. Material and Methods

In order to investigate the effects of the application of zinc, boron, and manganese (added to the soil and sprayed on the crop) on the extent of absorption of macro- and micronutrients in soybean seeds, an experiment in the factorial design with the two factors of adding the micronutrients to the soil and of spraying them on the crop was conducted in 16 treatments with four replications (a total of 64 trials). The treatments were as follows: T1=control; T2= Zn; T3= Mn; T4= B; T5=Zn; T6=Zn+B; T7= Zn+Mn; T8=Zn+B; T9=Mn; T10=Mn+B; T11=Mn+Mn; T12=Mn+B; T13=B; T14=B+B; T15= B+B; T16=B+B. Based on the soil test carried out, the required amounts of the micronutrients (40, 30, and 10 Kg.h of zinc sulphate, manganese sulphate, and boric acid, respectively) were added to the soil before seeding. The spray treatments were carried out using zinc (0.3%), manganese (0.30%), and boron (0.20%) at the start of stem elongation and at flower bud formation. Leaf samples at flowering and seed samples at seed maturity were taken and sent to the laboratory for analysis and determination of the concentrations of the elements.

3. Results

Seed Nitrogen Concentration

Results of the analysis of the variance of the data showed that the effects of adding different levels of the micronutrients to the soil (Factor A), at five percent probability, and the effects of spraying different levels of the micronutrients on the crop (Factor B) and the interaction effects of adding the micronutrients to the soil and spraying them on the crop (AB), at one percent probability, on seed

nitrogen percentage were significant (Table 1). Results of the comparison of the means indicated that, among the treatments of adding the micronutrients to the soil, the highest seed nitrogen concentration (6.57%) was achieved when manganese was added to the soil, and that this treatment had a statistically significant difference with the others. The treatment of adding boron to the soil came second with 6.33%, and the lowest seed oil concentration (6.29%) was that of the control. These results also showed that, among the treatments of spraying the micronutrients on the crop, the highest seed oil concentration (6.65%) was obtained when zinc was sprayed on the crop, and that this treatment was statistically different from the others. The lowest seed oil concentration (6.06%) was observed in the control (Table 3). Results of the interaction effects of the data indicated that the highest seed oil concentration (6.72%) was obtained by spraying zinc on the crop, and that the lowest seed oil concentration (5.65%) was observed in the control (Fig 1).

Seed Phosphorous Concentration

Results of the analysis of the variance of the data showed that the effects of adding the micronutrients to the soil (Factor A), the effects of spraying the micronutrients on the crop (Factor B), and the interaction effects of adding the micronutrients to the soil plus spraying them on the crop (AB) on the phosphorous concentration were not significant (Table 1). Results of the comparison of the means indicated that, among the treatments of adding the micronutrients to the soil, the highest seed phosphorous concentration (0.177%) was obtained when boron was applied to the soil, and that this treatment was not statistically different from the others. The treatments of adding zinc and manganese to the soil came second and third, respectively. The lowest seed phosphorous concentration (0.156%) was that of the control (Table 2). These results also showed that, among the treatments of spraying the micronutrients on the crop, the highest seed phosphorous concentration (0.183%) was achieved when zinc was sprayed on the crop, and that this treatment was not statistically different from the others. The lowest seed phosphorous concentration (0.175%) belonged to the control (Table 3). Results of the interaction effects of the data showed that the highest seed phosphorous concentration (0.225%) was observed when boron was added to the soil, and that the lowest seed phosphorous concentration (0.139%) was that of the control (Fig 2).

Seed Potassium Concentration

Results of the analysis of the variance of the data showed that the effects of applying the different

levels of the micronutrients to the soil (Factor A), and the effects of adding the micronutrients to the soil plus spraying them on the crop (AB) on the seed potassium concentration were significant at the five percent probability level, while the effects of spraying the different levels of the micronutrients on the crop (Factor B) on the seed potassium concentration were significant at the one percent probability level (Table 1). Results of the comparison of the means indicated that, among the treatments of applying the micronutrients to the soil, the highest seed potassium concentration (0.926%) was obtained when manganese was added to the soil, and that this treatment was not statistically different from the others. The lowest seed potassium concentration (0.839%) was that of the control (Table 2). Among the treatments of spraying the micronutrients on the crop, the highest seed potassium concentration (0.915%) was observed when zinc was sprayed on the crop; and this treatment did not have a significant difference with any other treatment except the control, in which the seed potassium concentration was 0.843 percent. In the treatments of spraying manganese and boron on the crop also, the seed potassium concentration was higher than 0.9 percent (Table 3). Results of the comparison of the interaction effects of the data showed that the highest seed potassium concentrations (0.930 and 0.945%) were obtained when zinc and manganese were sprayed on the crop, respectively. The lowest seed potassium concentration (0.631%) was observed when manganese was added to the soil (Fig 3).

Seed Zinc Concentration

Results of the analysis of the variance of the data showed that the effects of adding the different levels of the micronutrients to the soil (Factor A) on the seed zinc concentration were significant at the level of one percent probability, while the effects of spraying the different levels of the micronutrients on the crop (Factor B), and adding the micronutrients to the soil plus spraying them on the crop (AB) on seed zinc concentration were significant at the level of five percent probability (Table 1). Results of the comparison of the means indicated that, among the treatments of applying the micronutrients to the soil, the highest seed zinc concentration (52.5ppm) was obtained when zinc was added to the soil, and that this treatment was statistically different from the others. The treatments of applying manganese and boron to the soil came second and third with 45.92 and 45.58 ppm, respectively. The lowest seed zinc concentration (42.5ppm) was that of the control (Table 2). These results also showed that, among the treatments of spraying the micronutrients on the crop, the highest seed zinc concentration (51ppm) was

achieved when zinc was sprayed on the crop, and that this treatment had a statistically significant difference with the others. The lowest seed zinc concentration (44.42ppm) was also observed in the control (Table 3). Results of the comparison of the interaction effects of the data indicated that the highest seed zinc concentrations (55.33 and 55ppm) were obtained by adding manganese to the soil plus spraying it on the crop, and by adding zinc to the soil plus spraying it on the crop, respectively. The lowest seed zinc concentrations (29.33 and 30.1ppm) were observed in the treatment of adding manganese to the soil and in the control, respectively (Fig 4).

Seed Manganese Concentration

Results of the analysis of the variance of the data showed that the effects of the different levels of applying the micronutrients to the soil (Factor A) at the probability level of five percent, and the effects of spraying the different levels of the micronutrients on the crop (Factor B), and the interaction effects of adding the micronutrients to the soil plus spraying them on the crop (AB) at the probability level of one percent on the seed manganese concentration were significant (Table 1). Results of the comparison of the means indicated that, among the treatments of adding the micronutrients to the soil, the highest seed manganese concentration (23.08ppm) was obtained when manganese was applied to the soil, and that this treatment had a statistically significant difference with the others. The treatments of adding boron and zinc to the soil, with 22.5 and 21.75ppm, respectively, came second and third. The lowest seed manganese concentration (20.17ppm) belonged to the control (Table 2). These results also showed that, among the treatments of spraying the micronutrients on the crop, the highest seed manganese concentration (24.77ppm) was observed when manganese was sprayed on the crop, and that this treatment had a statistically significant difference with the others. The lowest seed manganese concentration (20.58ppm) was obtained in the control (Table 3). Results of the interaction effects of the data indicated that the highest seed manganese concentration (23.67ppm) was achieved by adding zinc to the soil plus spraying manganese on the crop, and by adding manganese to the soil plus spraying boron on the crop. These results also showed that the seed manganese concentration was observed to be 23ppm by applying boron to the soil plus spraying manganese on the crop, or by adding manganese to the soil plus spraying it on the crop. The lowest seed manganese concentration belonged to the treatment of adding boron to the soil (Fig 5).

Seed Boron Concentration

Results of the analysis of the variance of the data indicated that the effects of applying the different levels of the micronutrients to the soil (Factor A) at the probability level of five percent, and the effects of spraying the different levels of the micronutrients (Factor B) and the interaction effects of adding the micronutrients to the soil plus spraying them on the crop (AB) at the level of probability of one percent on seed boron concentration were significant (Table 1). Results of the comparison of the means showed that, among the treatments of applying the micronutrients to the soil, the highest seed boron concentration (46.58ppm) was achieved when boron was added to the soil, and that this treatment had a statistically significant difference with the others. The treatments of applying zinc and manganese to the soil, with seed boron concentrations of 36.67 and 36.83 ppm, respectively, came second and third. The lowest seed boron concentration (36.5ppm) belonged to the control (Table 2). These results also indicated that, among the treatments of spraying the micronutrients on the crop, the highest seed boron concentration (40.33ppm) was achieved when boron was sprayed on the crop, and that this treatment had a statistically significant difference with the others. The lowest seed boron concentration (34.92ppm) was observed in the control (Table 3). Results of the interaction effects of the data indicated that the highest seed boron concentrations (44 and 41.67 ppm) were obtained by spraying boron on the crop, and by adding manganese to the soil plus spraying boron on the crop, respectively. The lowest seed boron concentration (29.67ppm) was that of the control (Fig 6).

Abstract: The densification response of aluminium powder reinforced with nanometric SiC particles (50 nm) during uniaxial compaction was studied. To determine the effect of SiC nanoparticles on the compressibility of the matrix, monolithic Al powder was also examined. The effect of SiC nanoparticles on the densification mechanisms, i.e. particle rearrangement and plastic deformation, was analysed using modified Cooper–Eaton equation. The results showed that with increasing the reinforcement volume fraction (up to 20 vol.-%), the contribution of particle rearrangement increases whilst the plastic deformation is limited. At high compaction pressures, the reinforcement particles significantly influence the yield pressure of the composite powder, retarding the densification. The influence of the reinforcement particle size is discussed in this paper.

Keywords: Densification; Nanocomposite; Al/n-SiC; Non linear Compaction equation

1. Introduction

Discontinuously reinforced aluminium matrix composites have been developed and used for various applications, owing to their unique properties such as excellent wear resistance, high specific strength and thermal conductivity [1, 2]. Currently new development and research are focusing on the developing metal matrix nanocomposites with outstanding mechanical properties such as high yield strength and enhanced ductility [3-8]. In powder metallurgy techniques, the matrix and reinforcement particles are mixed and consolidated by various methods, e.g. hot deformation to fabricate almost full density products. Meanwhile, Kang et al. [9] have reported that the mechanical properties such as yield strength and hardness can be degraded by the reinforcement clustering, particularly at high volume fractions. Nevertheless, the compressibility of composite powders is remarkably lower than that of unreinforced matrixes [10]. In the past decades, considerable effort has been devoted to the development of empirical and theoretical compaction equations to describe the density–pressure relationships. By using linear compaction equations, such as Heckel[11], Panelli-Filho[12] and Ge[13], one can only study the role of plastic deformation (PD) on the densification response of composite powders. In order to study the role of particle rearrangement (PR), the non-linear equation proposed by Cooper and Eaton [14] was utilized [15]:

$$V^* = a_R \exp\left(\frac{-k_R}{P}\right) + a_P \exp\left(\frac{-k_P}{P}\right) \quad (1)$$

where V^* is the total fractional volume compaction, a_R and a_P are dimensional coefficients which indicate the fraction of theoretical compaction achieved at infinite pressure by each particle rearrangement (PR) and plastic deformation (PD) process, k_R and k_P are constants with units of pressure. The contribution of each mechanism on the densification can thus be evaluated by comparison between the magnitudes of the constants. Also, there are a number of valuable analytical and numerical models, for example Martin and Bouvard [16] and Kim et al. [17], which enable prediction of the compaction behaviour of composite powders.

So far, it is known that the densification of composite powders is similar to that of unreinforced metals, but they exhibit lower densification rate due to stress partitioning effect. The consolidation of Al matrix blended with hard nanoparticles have scarcely been studied and the densification mechanism is not well understood. Recently, the effect of nanoscaled reinforcement particles on the compaction behavior of Al-5vol. %Al₂O₃ has been reported by Simchi and co-workers [18]. The aim of present work is to study the effect of nano scaled SiC particles in a wide range of volume fractions on the consolidation behaviour of Al powder.

2. Experimental

Gas atomized aluminum powder with an average particle size of 40 μm was used as the starting matrix material. Nanometric SiC particles with the mean diameter of 40 nm was supplied from Alfa Aesar (Ward Hill, MA, USA). Different batches of Al-SiC

composite blends with varying volume fractions of 5, 10 and 20% were prepared. A Turbula mixer was employed for 30 min to prepare the blends. The tap density of powders was determined according to the ISO Standard 3953. The prepared powder blends were compacted in a cylindrical die with diameter of 15 mm using Teflon spray as die wall lubricant. In each run, 3 g powder was poured inside the die, taped and uniaxially compacted by using an AMSLER tensile/compression test instrument. The compacting pressure was varied between 10 to 400 MPa. The punch crosshead speed was 0.12 mm s^{-1} . Monolithic Al powder was also examined as the reference sample.

After ejection of compacts from the die, the density was measured by volumetric method. This method was employed through measuring the weight and dimensions of the compacts by using an accurate balance ($\pm 0.1 \text{ mg}$) and a micrometer ($\pm 0.1 \text{ mm}$). When the compaction pressure was low (for example $< 50 \text{ MPa}$) and a powder compact could not be attained, the in-die density was measured according to the mass and volume of the powder inside the die. Note that at such a low compaction pressure, the spring back is fairly low, thereby the difference between the in-die density and the out-die density is negligible. To investigate the consolidation mechanisms of matrix powder, the fracture surface of compacts were studied along the load direction. To prepare the suitable fracture surface, the compacts were sunk in liquid nitrogen. After bringing out the samples, they were immediately fixed and impacted to fracture. In order to fracture the specimens, a notch was prepared on the surfaces of each sample. Cooling the sample in liquid nitrogen results in brittle samples due to restriction of plastic deformation. The fracture surfaces were studied by SEM.

3. Results and Discussion

The Relative density of composite powders containing nanometric SiC particles at different compaction pressures is shown in Fig. 1. It is seen that, generally the addition of SiC particles decreases the compressibility of the Al matrix, so that compacts with lower relative density were obtained. Nevertheless, the densification of the composite powders at low pressure region ($< 50 \text{ MPa}$) is slightly higher than that of plain Al powder. This effect is more profound as the fraction of SiC increases. This can be attributed to the movement of SiC clusters to fill the interparticle pores. However, at high compaction pressures, the ceramic clusters and networks decrease the plastic deformability of the Al matrix, and thus retard the densification.

As it is seen in Fig. 1, at concentration $> 10 \text{ vol\%}$ SiC, the densification curves approach a plateau at

relatively moderate compacting pressures, indicating a high yield pressure of the nanocomposite powder.

Figure 1. Relative density of nanocomposite powders at various SiC volume fractions.

3.1. Analysis of compaction behavior using Cooper-Eaton equation

In order to investigate the role of SiC particulates on densification behavior of Al matrix powder, modified Cooper-Eaton equation in which, V^* is replaced by the porosity (ϵ) changes during compacting process [15], was used. The experimental results were evaluated according to equation (1), by means of non-linear least square method to determine the constants of the equation. The results are presented in Table I. It is noticeable that the correlation coefficient (R) is very close to unity, which indicates accuracy of the analysis.

Table 1. The compaction coefficients of Al-SiC nanocomposite powders calculated by modified Cooper-Eaton equation

SiC Fraction%	a_R	a_P	k_R [MPa]	k_P [MPa]	R
0	0.31	0.78	3.7	83.62	0.999
5	0.36	0.58	5.2	70.2	0.999
10	0.48	0.35	2.5	53.9	0.999
20	0.58	0.07	3.8	154.1	0.999

The results indicate a remarkable effect of nanometric particles on rearrangement and plastic deformation coefficients. Also it is worthy to point

out that the consistently higher values for k_P compared with k_R , are an indication that filling of voids in second stage of consolidation (plastic deformation), needs considerably higher pressures. According to experimental results presented in Table 1, it is apparent that the addition of nanosized inclusions, imposes a higher influence on the consolidation behavior of composite powders. To highlight this observation, the compaction behavior of Al-SiC composite powders containing nanometric SiC particles was analyzed.

The result of calculations is demonstrated in Fig. 2 that shows the contribution of PR and PD on the deformation capacity of Al matrix. It appears that with increasing the volume fraction of reinforcement, the contribution of PR on the densification was increased, whilst the contribution of PD was decreased. This effect is very pronounced, particularly when high amount of the reinforcement particles were introduced. The results indicate that when the fraction of nanometric particles is relatively high ($\geq 10\%$), the contribution of PD decreases significantly.

In this circumstance, plastic deformation has a very small contribution in compaction process and densification is mainly induced by PR rather than PD. For instance, the contribution of plastic deformation in total densification of composite compacts at volume fraction of 10 and 20% is about 42 and 10%, respectively.

Fig. 3 shows the relationship between the coefficients of Cooper-Eaton equation and the volume fraction of reinforcements. One can notice the great influence of the nanometric reinforcement particles on the tap density of the composite powder. This effect is marginal at the low volume fraction of 5%, but at higher percentages, a remarkable decrease in tap density is observed. Thus, the lower tap density provides greater space for particle sliding at the early stage of compaction [10]. Consequently, higher a_R values are calculated at higher volume fractions of SiC nanoparticles.

It is noteworthy that the clusters and agglomerates of nanoparticles can be disintegrated under the applied pressure to fill the interparticle voids. On the other hand, at high compacting pressures a_P decreases with increasing the SiC content, indicating a reduced contribution of plastic deformation on densification of the nanocomposite powder. In fact, it becomes difficult for the Al matrix to deform and fill the gaps between the ultra-fine particles; so, lower density is achieved.

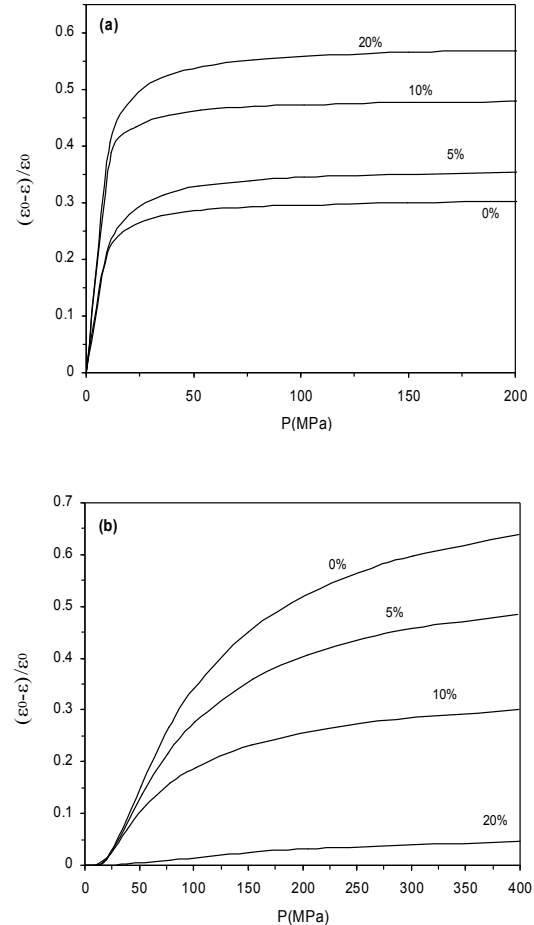

Figure 2. Effect of nano-sized SiC volume fraction on the contribution of particle rearrangement (a) and plastic deformation (b)

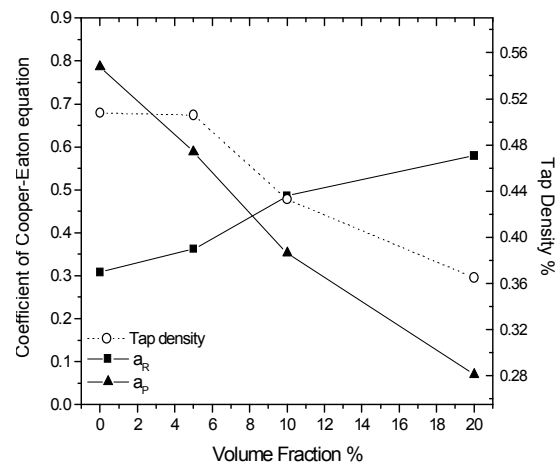

Figure 3. Effect of SiC nanoparticles on the tap density of Al powder and the coefficients of Cooper-Eaton equation.

Fig.4 indicates a profound effect of nanometric hard particles (Size ratio of 0.0025) on the tap density of composite powders. The ratio of the average size of SiC particles to the mean diameter of the Al particles are designated as the 'size ratio'. While this effect is marginal at low volume fraction of 5%, a significant decrease in the fractional density was observed at higher percentages. It is noticeable that with increasing reinforcement volume fraction, the detrimental influence of the nanoparticles increases.

Figure 4. Effect of reinforcement size and volume fraction on the tap density of composite powders.

The bilateral effect of the reinforcement size and volume fraction on densification of the composite powders is shown in Figure 5. As it is seen, the highest density is achieved at higher size ratios when the fraction of SiC is relatively low (<10 vol%). It means that above the percolation threshold (10 vol%), the size ratio should be increased; otherwise, the densification is significantly retarded.

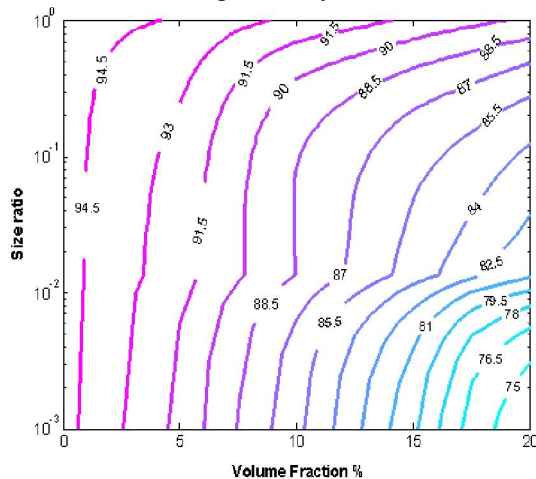

Figure 5. Effect of size ratio and volume fraction of the reinforcement on the density of composite powder at 300 MPa compacting pressure.

Fig 6. shows the representative SEM micrographs taken from the fracture surfaces of the Al powder compacted at 300 MPa. No evidence of ductile rupture, which is an indicator of the formation of large metal-metal contacts during pressing, is seen. The presence of the finer particles between the larger ones reveals that the applied load forced the spherical particles to move and fill the voids between the larger particles.

Figure 6. Fracture surface of Al powder compacted at 300 Mpa.

4. Conclusion

The consolidation behaviour of Al-SiC nanocomposite powders with varying reinforcement volume fraction during cold uniaxial compaction was studied. The results of Cooper-Eaton equation showed that with increasing the SiC content, the contribution of PR compared to PD increases. Meantime, the higher values for k_p compared with k_R , indicates that the filling of large holes (rearrangement stage) in the first stage of compaction, needs considerably lower pressures. This behavior is more pronounced in the case of composite compacts containing nanoscale SiC particles. This is owing to the low packing density, disintegration of clusters and the presence of particle size distribution in these composites. It was shown that at nano-scaled SiC concentration of ~ 8 vol%, the plastic deformation of aluminium particles is the important mechanism of the densification. At higher concentration of nano-sized SiC, the particle rearrangement was found to be the dominant mechanism of consolidation.
